Sportsman Satisfaction Survey Results: 81% Satisfied, 7% Neutral, 12% Dissatisfied

Herd Unit Issues

The management objective for the Chalk Bluffs Pronghorn Herd Unit numeric post-season population objective was changed starting the 2013 season to a landowner and hunter satisfaction survey. The change was based on public involvement during the 2013 herd objective review process. Classification is now collected to gauge pronghorn numbers and locations prior to the season opener.

There is not a postseason population estimate for a variety of reasons: 1) Open population with Colorado and Nebraska, 2) Restricted access due to urban encroachment and industrial gas development, which prevents our ability to influence harvest, 3) Poor classification data, which is always well below the adequate sample size and 4) No reliable working model.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout southeast Wyoming. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on all

big game species. For specific meteorological information for the Chalk Bluffs herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in Spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species.

In Spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field and Harvest Data

Due to our inability to collect data there is little confidence in classification data. In the adjacent Hawk Springs Herd Unit's fawn ratios increased, it was expected the same is true for this herd unit resulting in an increase in the population. However, without a reliable population estimate, interstate movement with Colorado, and an increase in industrial and residential expansion, license numbers will remain conservative. Type 6 license success in 2014 (55%) increased compared to 2013 (44%) but is still well below the five-year state average of 80%. Effort in 2014 (5.3 days/harvest) was similar to 2013 (5.8 days/harvest), but is also well below the five-year state-wide effort of 3.8 days/harvest. A combination of poor hunter success and increased effort coupled with limited access does not warrant an increase in Type 6 licenses for 2015. Type 1 licenses are proposed to remain at 100. A late season license will continue to be available to address damage concerns when pronghorn move in from Colorado. The landowner and hunter satisfaction survey showed that 85% of the sportsmen were either satisfied or very satisfied, and landowners were only 18% satisfied or very satisfied. However, a majority (55%) of the landowners were neutral on population size and did not want to see an increase or decrease in pronghorn numbers, indicating they are more or less satisfied with the population.

Management Summary

The opening date will remain the same at September 20 with no change in Type 1 and Type 6 license numbers. Landowners are still in favor of the late season hunt from November 15 – December 31 to address any damage concerns. Based on past seasons we predict a harvest of 50 bucks, 20 does and 10 fawns for a total of 80 pronghorn.

Management Evaluation

Current Management Objective: 6,000 (4,800-7,200)

Management Strategy: Recreational

2014 Postseason Population Estimate: ~7,800

2015 Postseason Population Estimate: ~6,900

Management Strategy: Recreational

Sportsmen Satisfaction Survey Results: 86% Satisfied, 6% Neutral, 8% Dissatisfied

Herd Unit Issues

The management objective for the Hawk Springs Herd Unit is a post-season population objective of 6,000 pronghorn. The objective was changed in 2014 from 7,000 to 6,000 and Hunt Areas 34-36 were combined into Hunt Area 34 as a result of the herd unit objective review process in 2013. The management strategy is recreational management with a pre-season buck ratio range of 20-59 bucks:100 does.

The 2014 post-season population estimate was about 7,800 pronghorn, placing the population 30% above the objective of 6,000 and an increase of 2,300 pronghorn from 2013. The last line-transect survey conducted in this herd unit was June 2007 that resulted in a population estimate of 21,000 pronghorn. This survey implied the herd increased by 62% from the previous line-transect conducted in 2003 with a population estimate of 8,100. Given poor fawn production, poor habitat conditions, and loss of habitat this estimate does not seem plausible. As a result this model is anchored to the 2003 line-transect estimate.

The southern end of the herd unit along Interstate Highway 80 to U.S. Highway 85 has experienced an increase in urban and industrial development resulting in a decrease in usable habitat. The northern 2/3 of the unit is comprised of dryland farming, irrigated farming, land enrolled into the Conservation Reserve Program (CRP) and native rangeland. The majority of issues with landowners occur when there are high densities of pronghorn on irrigated and non-irrigated agricultural fields. This typically results in damage issues which is the rationale behind the late season doe/fawn licenses.

A majority of this herd unit is comprised of private land (84%). Access is available through the Department's PLPW program and limited access to 350 square miles of state land.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout southeast Wyoming. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on big game species. Mild fall temperatures and lack of persistent snows allowed for pronghorn to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Hawk Springs Pronghorn Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern

over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In Spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

This herd increased in 2014 as a result of above average fawn production in 2014 (64 fawns:100 does) compared to the five-year average of 47 fawns:100 does and reduced harvest pressure on the female segment of the population. Doe/fawn license issuance has fluctuated around 750 for the past 5 years and was decreased in 2014 to try and increase the population, which was accomplished by 30%. Buck ratios were similar compared to 2013 but are still within the recommended recreational management range 20-59 bucks: 100 does (43 bucks:100 does in 2014). However, limited access prevents additional opportunity to put hunters in the field. The sample size for field check tooth data collected in the field was too small to provide any reliable estimates for population parameters. The age data collected indicates the majority of male pronghorn are 3 years or older, which is typical of hunters looking for a mature buck. Females range from 1+ to 3+ which is plausible given there is not a way for hunters to judge the age of females in the field. Of the hunters surveyed in 2014, 86% were satisfied with their hunt. Based on comments in the field during the 2014 hunting season hunters had more success accessing private land and they appreciated the number of acres enrolled into the PLPW program.

Harvest Data

Active license success of 84% in 2014 was higher than five-year average of 78% and slightly higher than the five-year state-wide average of 82%. There is still difficulty finding access in the southern portion of the herd unit, but access did open up with the Nimmo HMA and private land in the northern portion of the herd unit, which could explain the increase in success. Hunter effort (4.0 days per harvest in 2014) was slightly lower than the five-year average of 4.4 days per harvest but slightly higher than the five-year state-wide average of effort of 3.8 days. Factors impacting success most likely contributed to a decrease in harvest effort.

Population

The “Constant Juvenile – Constant Adult Survival” (CJ,CA) spreadsheet model was chosen for the post season population estimate of this herd. The model did have the lowest AIC score, and the population estimate appears reasonable. The line-transect in 2007 was ignored and the independent estimates of 2001 and 2003 are similar to model estimates. The model predicted a decreasing trend since 2007, but increased in 2014; given increased fawn production and a decrease in female harvest compared to the past five years this seems plausible. WGFD personnel observations indicate that pronghorn densities would support this trend. Some landowners still feel there are too many pronghorn but the amount of damage has decreased in

the last 2-3 years. Trends in harvest statistics (increase in success, and a decrease in effort) seem to support model simulations of a sudden increase in the population. This model is ranked fair since the only data available is harvest and classification data and the most recent LT estimate is from 2003.

Management Summary

The 2014 season is designed to try and decrease the population with an additional 100 Type 1 licenses and 200 Type 6 licenses. Given previous harvest rates and the 1,600 licenses available (900 Type 1 licenses, and 700 Type 6 licenses) we expect to harvest around 1,210 pronghorn, resulting in a post-season population estimate of 6,900 pronghorn.

Management Evaluation

Current Management Objective: 5,000 (4,000-6,000)

2014 Post-season Population Estimate: ~5,000

2015 Post-season Population Estimate: ~4,800

Management Strategy: Recreational

2014 Sportsmen Satisfaction Survey Results: 89% Satisfied, 12% Neutral, 3% Dissatisfied

Herd Unit Issues

The management objective for the Meadowdale Pronghorn Herd Unit of 6,000 was decreased to 5,000 as a result of internal and public input received during the 2013 herd objective review process. The management strategy is recreational management, which is a 20-59 buck:100 doe range.

The 2014 post-season population estimate was about 5,000 with the population trending down from the high of 7,000 pronghorn in 2004. The last line-transect was conducted in June of 2003 that resulted in an estimate of 5,800 pronghorn. The northern portion of the herd unit continues to have the highest densities of pronghorn resulting in more acres of private lands enrolled into the PLPW walk-in program as well as landowners opening access, particularly during the doe/fawn season.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant

prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on big game species. Mild fall temperatures and lack of persistent snows allowed for pronghorn to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Meadowdale Proghorn Herd Unit the reviewer is referred to the following link:
<http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

The Meadowdale population has been stable to decreasing since 2004. In 2014 fawn ratios (65 fawns: 100 does) increased compared to the five year average of 57 fawns:100 does. The sample size was only 5% below the 90% CI so herd classification data appears to be plausible. The 2013/14 winter was mild and most likely did not result in high winter mortality. Fawn ratios were similar to adjacent herds, but given excellent habitat conditions during fawn rearing periods a more dramatic increase was expected. Lingering affects to body condition on breeding does from the 2012 drought might have possibly led to lower conception rates and survival. Buck to doe ratios have fluctuated from a low of 28:100 to a high of 59:100 within the last ten years. The 2014 buck ration was 34 bucks:100 does, which seems reasonable given the sample size. Low fawn recruitment and seasons designed to reduce the population have resulted in a decreasing population trend, placing the population within the population objective of 5,000 pronghorn. With the population at a desired level there is not a proposal to increase Type 6 licenses, and given buck ratios are within the recommended recreation management strategy parameters there is not a proposal to increase Type 1 licenses. Sample size for tooth data collected in the field is too small to infer any population dynamics.

Harvest Data

The 2014 hunter success rate (93%) was similar to the ten-year average of 91%, but significantly higher than 2013 (74%). Fewer hunters went to the field in 2014 since Type 6 licenses from Hunt Area 9 were not valid in the northern portion of Hunt Area 11, decreasing in harvest in 2014 compared to 2013. Effort in 2014 was 4.2 days per harvest which is higher than the five-year average of 3.4 days per harvest, but similar to 2013 (4.2 days/harvest). Harvest statistics (increase in success, stable effort) support a population that experienced a slight increase from 2013 to 2014. Five-year trends in success (decrease) and effort (increase) supports the models simulation that the population is experiencing a downward trend. However, population assumptions must be interpreted with caution due to movement in and out of Area 11 from Hunt Area 9. At any given time there could be an increase or decrease of pronghorn depending on movement across Highway 18/20. The hunter satisfaction survey showed that 89% of the hunters were satisfied or very satisfied with their hunt. Based on positive comments received from the field the survey seems plausible.

Population

The “Constant Juvenile – Constant Adult Survival” (CJCA) spreadsheet model was selected for the post-season population estimate of this herd. This model did have the lowest AIC score, the second best fit and the population estimate appears reasonable. We conducted line-transects in 1996, 1998, 2000 and 2003 that provide independent population estimates that were similar to the model estimates. Based on relatively consistent harvest regimes and classification surveys this population typically fluctuates around 4,500 pronghorn, (2014 post-season estimate: 5,000 pronghorn) and has not experienced a significant increase or decrease in the past 5 years. This model is ranked fair since the last LT this population was anchored to was conducted in 2003, and the only other data available is harvest and classification data. WGFD personnel, landowner and hunter observations indicate that pronghorn densities remain low in the southern portion of

the hunt are and high in the northern portion. Landowners in that portion of the herd unit have damage problems and have voiced their concern at several Department meetings over the past two years.

Management Summary

The 2014 season was designed to maintain the population within the objective, which is the same goal for the 2015 season. Given previous harvest rates we expect to attain a harvest of 415 pronghorn. We predict a 2015 post-season population estimate of 4,800 pronghorn, 4% below the objective of 5,000, but within the $\pm 20\%$ recommended range for herd management.

Management Evaluation

Current Postseason Population Management Objective: 13,000 (10,400-15,600)

Management Strategy: Recreational

2014 Postseason Population Estimate: 11,200

2015 Proposed Postseason Population Estimate: 11,600

2014 Hunter Satisfaction: 86% Satisfied, 10% Neutral, 4% Dissatisfied

The management objective for the Iron Mountain Pronghorn Herd Unit is a post-season population objective of 13,000 pronghorn. The management strategy is recreational management with a post hunt buck ratio of 30 to 59:100 does. The objective and management strategy was last revised in 2014.

Herd Unit Issues

The Iron Mountain Herd Unit consists of Hunt Areas 38, (combined 39, 40 and 104 into Hunt Area 38 in 2014) which is predominately private lands with traditional agricultural uses. The 2014 post-season population estimate was 11,200 with the population trending slightly upward. Access limitations hinder our ability to manage this herd. Efforts to increase harvest in accessible areas have resulted in reduced success and decreased hunt quality.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts

of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific weather information please refer to the following link: <http://www.ncdc.noaa.gov/>.

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

A total of 2,019 pronghorn were classified, which is slightly below the recommended classification objective of 2,094, but 700 more than in 2013. Drive routes have been established in this herd unit so that some inference can be made from a trend in classification samples year to year. Fawn ratios increased from 60 fawns: 100 does in 2013 to 86 fawns: 100 does in 2014 which is the highest on record for this herd. Buck ratios declined from 58 bucks: 100 does in 2013 to 49 bucks: 100 does, which is still higher than average, but we didn't see the large increase in yearling bucks like we did in neighboring herds. The hunter satisfaction survey showed 86% of hunters were either satisfied or very satisfied with their hunt which is an increase from 78% in 2013.

Harvest Data

Hunters had an exceptional year in this herd unit, indicated by the highest hunter success in over a decade at 88% and an increase of 10% from 2013. This is also indicated by days-to-harvest decreasing by a day to 3 days which is also the lowest in 10 years. This herd is typically a low

priority area for resident hunters, due to lack of public access, and many of the licenses are purchased after the draw by nonresidents, 64% of the license holders. Since this is the first year after combining all the hunt areas in the herd unit into one, we kept the license quota in 2014 equal to 2013. In 2013 we had 728 licenses left after the draw, in 2014 we only had 230 type 6s. From 2013 to 2014 total active licenses increased by 55, and overall harvest increased by 200 pronghorn.

Population

The population has remained fairly stable with the population increasing in 2014 due to a record fawn ratio. The spreadsheet model for this herd estimates a post hunt population of 11,200. This estimate uses the Constant Juvenile & Adult Survival model which had a AIC score of 28 and a best fit score of 18. This is a poor model due to little data available; ratio data, if available, considered highly biased because of poor sample sizes or an inability to survey the entire area; results not biologically defensible. To get the model to run we truncated years to 2002 to eliminate years of poor classification data. We also did not include LT estimates as they are also of poor quality due to such large deviations in terrain height resulting in large standard errors. Field staff and landowners are happy with current numbers and believe the population is fairly stable.

Management Summary

This herd has always been hard to manage due to limited population data and a large percentage of inaccessible private lands. We combined Hunt Areas 38, 39, 40 and 104 in 2014 to simplify regulations and allow hunters more opportunity to move where the pronghorn are most accessible. It appears to be working from the increase in hunter success to record levels. Licenses sold out for the first time in this herd unit in 2014; it is not completely clear why, but we suspect it is due to the large decrease in licenses state wide led to hunters drawing 38 as a second and third choice. Therefore we will leave license issuance as status quo so that we may look at a longer trend and reevaluate in 2016.

Management Evaluation

Current Management Objective: 4000 (3,200-4,800)

2014 Post-season Population Estimate: ~3,300

2015 Post-season Population Estimate: ~3,500

Management Strategy: Recreational

2014 Sportsmen Survey Results: 78% Satisfied, 11% Neutral, 11% Dissatisfied

Management Issues

The management objective for the Dwyer Pronghorn Herd Unit is a post-season population objective of 4,000 pronghorn. The management strategy is recreational management with a 20-59 buck:100 doe ratio range. The herd objective and management strategy was reviewed in 2014 and to the decision was made to maintain the same population objective of 4,000 pronghorn and recreational management.

The 2014 post-season population estimate of 3,300 decreased by 14% from 2013. This population had been trending downward from a high of 4,750 in 2009. The last line-transect survey with a density estimate was conducted in June 2003 and resulted in an estimated population of 5,800 pronghorn. A line-transect was flown at the end of the 2013 biological year, but results are not available at this time.

There has been little urban and industrial development within this herd unit. The herd unit is comprised of 90% private land and some accessible state land. Land use is comprised of native range land, irrigated and dry land agriculture fields, and land enrolled into the Conservation Reserve Program (CRP). The majority of access is in the northern portion of the herd unit via the PLPW program and private land opened up address damage situations.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on pronghorn. Mild fall temperatures and lack of persistent snows allowed for pronghorn to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Dwyer Pronghorn Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in Spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In Spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

This herd has been declining since 2009, which is most likely a result of poor fawn production. There was a slight increase in fawn production in 2014 (52 fawns:100 does) compared to the five-year average of 47 fawns:100 does, but well below what was expected compared to adjacent herds given excellent habitat conditions. Low recruitment undoubtedly has some negative effect on pronghorn population performance.

Buck ratios have fluctuated from a low of 30:100 to a high of 64:100 in the last ten years, well within recreational management levels. When interpreting fawn and buck ratio trends, data needs to be interpreted with caution. Only five out of the past twenty years has the sample size been met or exceeded to 90% CI. However, even with poor classification data the population models have been anchored to LT estimates to provide a plausible population estimate.

Hunter participation was 73% for 2014, a decrease of 9% compared to 2013. Access continues to be an issue in a private land dominated herd unit. Sample size for tooth data collected in the field is too small to infer any population dynamics.

Harvest Data

Hunter success has dropped in the past two years for both Type 1 and Type 6 licenses while effort has remained fairly stable. Private land access has remained stable, Walk in Areas (WIAs) were lost in the southern portion of the unit while a new HMA was gained. In addition some access has opened up in central portion of the herd unit, but due to crop conversion access was lost in the northern portion. The hunter satisfaction survey showed that 78% of the hunters were either satisfied or very satisfied with their hunt, a slight decrease compared to 2013 (85%). Loss of hunting opportunity most likely affected hunter attitudes.

Population

The “Time Specific Juvenile- Constant Adult Survival” (TSJ, CA) spreadsheet model was chosen over the simpler Constant Juvenile-Constant Adult (CJ,CA) model and resulted in a post-season population of 3,300 pronghorn. Without a 2013 end-of-the-year population estimate, derived from a Line Transect, the CJ,CA models predicts the population to crash. By allowing for a variation in juvenile survival the TSJ,CA model runs through three out of the past four Line Transect estimates and provides a plausible population estimate. Harvest statistics in conjunction with no pronghorn die-offs observed indicate the population has not crashed as simulated by the CJ,CA model. The CJ,CA AIC score was slightly lower than the TSJ,CA score, but the TSJ,CA has a better fit than the CJ,CA model. A line-transect was completed in June, 2014 but results are not available at this time to assist with model simulations. This model is ranked fair since the last LT was ran back in 2004 and the only other data available for the model is classification and harvest data.

Management Summary

There will be no changes in the opening and closing dates of the Type 1 and Type 6 licenses.

The Type 7 license was left out of the 2015 packet and was deleted for the 2015 season.

Reduced damage, herd management simplification and more hunter flexibility to hunt does and fawns are the main reasons to remove the Type 7 license. The number of Type 6 licenses was increased from 250 to 350 to take into account the removal of the Type 7 license and maintain the population within the objective. Type 1 licenses will remain the same. Buck ratios remain within recreation parameters with the current harvest structure.

If the projected harvest of 510 pronghorn is attained coupled with normal fawn recruitment, the pronghorn population should slightly increase to 3,500, 13% below the objective of 4,000.

Management Evaluation

Current Postseason Population Management Objective: 45,000 (36,000 – 54,000)

Management Strategy: Recreational

2013 Postseason Population Estimate: ~ 33,500

2014 Proposed Postseason Population Estimate: ~ 34,200

2014 Hunter Satisfaction: 82% Satisfaction, 11% Neutral, 7% Dissatisfied

The management objective for the Medicine Bow Pronghorn Herd Unit is a postseason population objective of 45,000. The management strategy is recreational management which requires maintaining for buck ratios of 30 to 59:100 does. The objective and management strategy were last revised in 2014.

Herd Unit Issues

The Medicine Bow Herd Unit encompasses hunt areas 30, 31, 32, 41, 42, 46, 47 and 48. These hunt areas vary between predominantly public land and exclusively private land. Large scale wind farms and coal mining within this herd may be negatively impacting habitat and productivity. The population has been on a decline from a high of 49,700 in 2004 until 2014 when it increased to 33,500 from 25,000 in 2013. In the early 2000's the Department was trying to reduce the population below the objective of 60,000 to try and improve poor habitat conditions in the Shirley Basin and Bates Hole areas. At the same time this herd was hit hard by harsh winters, drought, and disease, causing the herd to decline below 30,000 pronghorn. The population is still not acceptable to the public or landowners and we are managing this herd to increase the population. The herd objective was reviewed in 2014 and was changed to a post season population objective of 45,000 pronghorn. This will still allow the herd to increase substantially and at the same time manage for fewer pronghorn so that habitat conditions are not as overutilized.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in received the highest amount of precipitation on record. 2014 experienced a mild winter, above

average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. The herd unit received a significant snow storm in May that left 3 to 4 feet of snow that melted quickly, but may have had a negative impact to the herd. For specific weather information please refer to the following link: <http://www.ncdc.noaa.gov/>.

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Field Data

A total of 5,668 pronghorn were classified in 2014, exceeding the estimated classification objective of 2,598. Classification methods were changed from aerial to ground in 2013. Drive routes were established so that some inference can be made from classification samples year to year. Buck ratios had been on a steady decline since 2011 when it was 58bucks:100 does to 34 bucks:100 does in 2013. In 2014 buck ratios increased to 43:100 does. Interestingly yearling bucks increased, making nearly half the bucks counted, while adult bucks remained near past year's levels. Herd unit wide fawn ratios increased to 71:100 does, and while most hunt areas saw an increase in fawn ratios, some were still lower than average, and 2 hunt areas (31, 48) saw a decline. This herd unit did not see the large increase in fawn ratios like some neighboring herds, but it has more of a shrub component while neighboring herds are mostly grassland prairie. This could be due to grassland habitats ability to respond quicker to increases in precipitation than shrub communities. The large increase in yearling bucks throughout the herd unit indicates that we have a large yearling class and yearling does would not have had a fawn in 2014 which would have also brought down the fawn ratio. In 2014 we aged 237 harvested pronghorn, of which 25% were yearlings, an increase of 10% over the last 5 years. The hunter satisfaction survey shows 82% of hunters were either satisfied or very satisfied with their hunt with 11% remaining neutral, which is comparable to past years.

Harvest Data

Hunter success for all active licenses types increased to near the 10 year average of 82% after a 3 year decline, and hunter effort declined slightly to 3.3 days. We expected more of an increase after cutting 3,400 licenses. Some herd units such as 46 and 47 saw an increase in hunter success to near 90%, while the rest saw only moderate increases. Success on type 6 and 7 licenses was below 70%, and in some cases below 50% even though very few licenses were issued. Even with the significant cut in licenses the last 3 years and the recent increase in fawn ratio, it will take several good production years before we near the population objective and are once again able to provide more hunting opportunity.

Population

The spreadsheet model for this herd indicates the population is increasing with a post hunt population of 33,500. This estimate was derived using the time-Specific juvenile and Constant Adult Survival model which had a AIC score of 274 and a best fit score of 172. The last line transect was conducted in 2011 with an estimate of 31,132 with a standard error of 4,328. The model is of good quality, predicted end of year population trends align well with past line transect estimates, and is comparable with what field personnel have noted from landowner and hunter comments. The model has 15-20 years of data; ratio data available for all years in model; juvenile and adult survival estimate with standard errors available at least 2 out of 10 years (Grogan et al) and at least one sample-based population estimate with standard error available.

Management Summary

If the projected harvest of 2,100 is attained, and the average fawn ratio of 70 fawns: 100 does is maintained, the population is estimated to increase to 34,200. If we have another good year for spring and fall moisture, and fawn production increases like what we have seen in surrounding herds, the population will increase more substantially. License issuance has been decreased to the point that we no longer need to spread out hunting pressure on reduced price licenses. We removed all type 7 licenses, and due to the poor hunter success we only added them to the type 6 quota in hunt area 47. Type 6 licenses will be increased by 50 licenses in hunt area 32 to further address damage issues that occur when pronghorn from northern Shirley basin move into Bates Hole. Hunt area 41 will be combined into 42 in 2015, and we will be leaving the license issuance for 42 as status quo without the addition of 41 licenses due to the decline in hunter success. We are seeing a good increase in productivity and hunter success in most of the hunt areas but hunt area 48 appears to be in poor condition with low fawn recruitment and poor hunter success therefore we cut Type 1s and 2s by 50 each.

Management Evaluation

Current Postseason Population Management Objective: 3,000 (2,400-3,600)

Management Strategy: Recreational

2014 Postseason Population Estimate: ~ 4,900

2015 Proposed Postseason Population Estimate: ~ 4,600

2014 Hunter Satisfaction: 84% Satisfied, 11% Neutral, 5% Dissatisfied

The management objective for the Cooper Lake Pronghorn Herd Unit is a post-season population objective of 3,000 pronghorn. The management strategy is recreational management with a buck ratio of 30 to 59:100 does. The objective and management strategy was last revised in 2013.

Herd Unit Issues

The 2014 post-season population estimate is 4,900, an increase from 4,200 in 2013. The long term population has been trending downward since 2008. The last line transect was conducted in 2013. This herd is predominately private land with increasing urban sprawl near Laramie, and a large wind farm in the western portion of the herd. Limited public access has hindered efforts to decrease this herd through harvest. Currently most public hunting is limited to the Diamond Lake and Laramie River Hunter Management Areas (HMA) which encompasses half of the herd unit, but we lost a large piece of property in the middle of the HMA. Field staff has documented Epizootic Hemorrhagic Disease (EHD) in the herd unit in 2012 and 2013. A snow storm in May 2014 left 3 to 4 feet on the ground throughout the herd unit and appears to have killed off some of the older senescent age classes.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an

average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. The Laramie Valley did receive a significant snow storm in May that left 3 to 4 feet of snow that melted quickly, but may have had negative impacts to this herd. For specific weather information please refer to the following link:

<http://www.ncdc.noaa.gov/>.

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Field Data

A total of 800 pronghorn were classified which is below the estimated sample size of 1,500. Classification samples have been below the estimated sample size since 2006. Fawn ratios increased greatly from 77:100 in 2013 to 101 fawns:100 does in 2014. The increase is comparable to other surrounding herds but may be inflated due to a loss of older senescent does from the late May snow storm. Drive routes have been established so that some inference can be made between classification samples year to year. We classified almost the same number of pronghorn in 2013 and 2014 but in 2014 we saw the same number of fawns and 100 less does. Buck ratios had been on a decline due to drought conditions and disease, but in 2014 we saw the ratio double from 31 bucks:100 does in 2013 to 66 bucks:100 does in 2014. We saw a significant increase in both yearling and adult bucks but yearlings made up half the classification sample.

Harvest Data

We issued 850 licenses which did not completely sell in the resident draw but were picked up after the draw by non-residents, who account for 80% of the licenses sold. Hunter success declined for both license types with type 1s declining from 87% in 2013 to 83% in 2014, and the type 6's declined from 84% in 2013 to 70 % in 2014. We lost a large property from one of the HMAs that created a refuge in the middle of the HMA and may have caused hunter success to decline. Hunters had more favorable weather in 2014 and we think that is why hunter effort declined by a day to 3 days to harvest. The hunter satisfaction survey showed 84% of hunters

were either satisfied or very satisfied with their hunt which has been declining since 2012 when it was at 94%.

Population

The model estimates the population is near 4,900 pronghorn and predicts it will decline to 4,600 in 2015. Fawn ratios for this herd exceeded estimates from last 20 years and we saw a large jump in the population estimate from 2013 to 2014 after it had been on a steady decline since 2008. The Constant Juvenile- Constant Adult Mortality Rate (CJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. The model chosen had the lowest AIC of all three models and the end of year population estimate trends well with the past LTs. We conducted a line transect in June 2014 that estimates an end of bio year estimate of 7,000 with a standard error of 1,200. The histogram for this survey shows that the E band is higher than the B, C or D bands, and therefore breaks the first assumption. This is a poor model due to ratio data, if available, considered highly biased because of poor sample sizes or an inability to survey the entire area; lacks adult and juvenile survival data; results not biologically defensible.

Management Summary

With the current amount of public access and a predicted harvest of 640 pronghorn, the model predicts that the population will again decline towards the management objective. Modeling efforts predict a 2015 post-season population of about 4,600. Harvest in this herd largely relies on two large HMAs in the hunt area which have been instrumental in moving this population towards objective. With the current number of licenses issued the herd should gradually reach the objective with a smaller chance of over harvesting.

Management Evaluation

Current Postseason Population Management Objective: 14,000 (11,200 – 15,800)

Management Strategy: Recreational

2014 Postseason Population Estimate: ~ 11,700

2015 Postseason Population Estimate: ~ 11,200

2014 Hunter Satisfaction: 88% Satisfied, 6% Neutral, 5% Dissatisfied

The management objective for the Centennial Pronghorn Herd Unit is a post-season population of 14,000. The management strategy is recreational management requiring a buck ratio of 30 to 59:100 does. The objective and management strategy was last revised in 2013.

Herd Unit Issues

The Centennial Pronghorn Herd Unit encompasses Hunt Areas 37, 44, and 45 which are predominately private land with little public access. The 2014 post-season population estimate was approximately 11,700 with the population trending slowly downward from 18,000 in 2004. The last line transect was conducted in 2013. Harvest strategies are designed to maximize harvest where possible. Most of the harvest is limited to Hunter Management Areas (HMA) where the threshold of hunter densities has been reached and an increase in license issuance may decrease harvest. This herd has experienced loss of habitat from an increase in subdivisions, and a wind farm is scheduled to be developed in Hunt Area 44 near the Colorado border, which may also cause a loss of access. There is significant interchange with Colorado. Most if not all of the

pronghorn in hunt area 37 winter in Colorado, while it is also thought most of the pronghorn in the Laramie River valley in Colorado winter in hunt area 44.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. The Laramie Valley did receive a significant snow storm in May that left 3 to 4 feet of snow that melted quickly, but may have caused a die off consisting of mostly older senescent age classes. For specific weather information please refer to the following link: <http://www.ncdc.noaa.gov/>.

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Field Data

A total of 2,626 pronghorn were classified, 700 more than in 2013, and exceeding the estimated classification objective of 2,150. Classification routes have been standardized so that some inference can be made from year to year classifications, and we saw an increase in pronghorn through all 3 hunt areas. Fawn production saw a large increase in 2014 to 79 fawns: 100 does, an increase of 18 fawns: 100 from 2013. Fawn production varied greatly by hunt area, 45 being the highest at 92 fawns: 100 does, and hunt area 37 being the lowest at 65 fawns: 100 does, but still a large increase in fawns for both hunt areas. Buck ratios increased from 36 bucks: 100 does in 2013 to 50 bucks: 100 does in 2014; however the number of mature bucks remained stable while there was a large increase in yearling bucks.

Harvest Data

Hunter success increased to 84% in 2014, an increase of 9% from 2013, and equal to the 10 year average. All three hunt areas saw increases in hunter success across license types; however hunt area 37 type 6 success still remains below 80%. It appears that the reduction in licenses in 2014 provided the relief needed to increase hunter success to near the 10 year average. The Hunter Satisfaction Survey showed 88% of hunters were satisfied or very satisfied with their hunt with 6% of respondents remaining neutral. The biggest challenge is trying to manage harvest on the few accessible public lands and HMAs without decreasing the quality of the hunt and abundance of game.

Population

The Constant Juvenile – Constant Adult Mortality Rate (CJCA) spreadsheet model was chosen to use for the post season population estimate of this herd. This model did not have the lowest relative AIC score but had the most reasonable population estimate, and considering the issue with herd data, we wanted to use the simplest model. To get a model to run the years were truncated to 2000. The model estimates the Centennial pronghorn herd has slowly trended downward since 2004 when the population was estimated at 18,000, and is currently near the population objective. This is a poor model due to ratio data, if available, considered highly biased because of poor sample sizes or an inability to survey the entire area; significant interchange with populations in Colorado; lacks adult and juvenile survival data; results not biologically defensible. We conducted a line transect survey for this herd in the spring of 2014 which estimates 21,009 pronghorn with a standard error of 3,300. The CI is between 15,370 and 28,700 pronghorn. E band estimates are too high and violates the first assumption of the LT survey.

Management Summary

A confounding influence is that some segments of the herd move back and forth between Colorado and Wyoming. In the past we have not been able to manage this herd through harvest due to high fawn ratios and limited access. We estimate the population has been reduced by half since 2004 and we are near objective. With the high fawn ratios and mild winter, we expect the herd will start increasing. We will maintain the current number of licenses that were issued in 2014 as we believe we have reached a good balance with hunter densities on public land and HMAs. We will extend the season to the end of October in hunt areas 44 and 45 to provide more opportunity by spreading out hunting pressure and we expect to see an increase in hunter success. If we attain the projected harvest of 1,000 pronghorn and have fawn ratios near 70 to 75, the population will remain near the objective. We predict a 2015 post-season population of approximately 11,200.

Management Strategy: Recreational

2014 Postseason Population Estimate: 3,000

2015 Proposed Postseason Population Estimate: 3,100

2014 Hunter Satisfaction: 89% Satisfied, 5% Neutral, 6% Dissatisfied

Pronghorn in the Elk Mountain herd unit are managed toward a numeric objective of 5,000. The population was estimated using a spreadsheet model developed in 2012 and updated in 2015. The herd is managed for recreational opportunity. The objective was reviewed in 2014 and retained at a postseason estimate of 5,000 pronghorn (Appendix A).

Herd Unit Issues

The Elk Mountain herd unit is comprised predominantly of either private or land-locked public land. Hunter access to these lands is limited, particularly east of Elk Mountain, where most pronghorn in this herd unit are found during the hunting season. Private lands open to hunters receive a large amount of pressure. Much of the herd unit's sagebrush ecosystem remains intact. However, increased agricultural, energy, and residential development does threaten the sagebrush habitat in this area.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred

transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on pronghorn. Mild fall temperatures and lack of persistent snows allowed for pronghorn to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Elk Mountain herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 was recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

Preseason ratios for this herd were 34 bucks and 45 fawns/100does in 2014. Buck ratios and fawn ratios both increased in recent classification trend. Traditionally, classification data in this herd unit had been collected from fixed-wing aircraft. Beginning in 2011, classification surveys have been conducted from the ground and have lower sample sizes than those previously completed from fixed-wing aircraft. The ground surveys also may contain more sampling biases in comparison with surveys conducted prior to 2011 due to limited data from more remote areas of the herd unit.

Harvest Data

The 2014 harvest survey indicated a total of 347 pronghorn were harvested which was a decrease of 50% from 2013. Overall harvest success increased 15% to 100% for 348 active licensed hunters in 2014. The days/pronghorn decreased slightly from 3.7 to 3.2 days/harvest. The increase in harvest success and decrease in day/harvest was attributed to the decreases in license numbers made in 2014, as a means to balance hunter opportunity with a decreased population size.

Population

Spreadsheet model estimates indicated the Elk Mountain herd is currently below the management objective of 5,000 pronghorn. The CJ, CA model was selected again for the Elk Mountain herd unit in 2014. The model's population estimates are plausible and match trends in harvest and preseason classifications. The model's end-of-year estimates are less than corresponding year Line-Transsect survey density estimates in 2007, 2010, and 2012. A portion of the Elk Mountain herd unit was used as a control area for the University of Wyoming's Dunlap Wind Farm research project. We incorporated adult survival rates from this research into the model for bio-year 2010 and 2011.

We rated this model as fair, and biologically defensible in our evaluation. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model (Morrison 2012).

Management Summary

The Type 6 license numbers were reduced again for the 2015 season. Liberal seasons in the recent past and severe winters have reduced pronghorn numbers in this herd unit over the past 5 years. The decreased license numbers will assist in increasing the population toward the management objective. The popular muzzleloader only season continued to be offered in 2015.

2014 ELK MOUNTAIN PRONGHORN HERD UNIT AND POPULATION OBJECTIVE REVIEW

Prepared by: Will Schultz, Saratoga Wildlife Biologist

The Elk Mountain pronghorn herd unit is located in south-central Wyoming, south of US Interstate 80, between the North Platte River and Rock Creek, and is bordered by the Snowy Range Mountains to the southeast (Figure 1). The Elk Mountain pronghorn herd unit occurs entirely within Hunt Area 50, and contains 1,572.6 km² of occupied habitat. The occupied habitat consists primarily of sagebrush grassland and mountain shrub habitat types, with irrigated hay meadows occurring on private lands.

Figure 1. A map of the Elk Mountain pronghorn herd unit and Hunt Area 50 located in south central Wyoming.

Approximately 65% of the herd unit is privately owned. The predominant use of the land in the herd unit is cattle grazing. Energy and urban development has been minimal in this herd unit. However, conversion of suitable pronghorn habitat to rural residential development has occurred east of the town of Saratoga in recent decades.

Although pronghorn can be found throughout suitable habitat year-long, they tend to migrate to lower elevations in the western part of the unit to winter, and migrate to higher elevations in the east to summer. Traditional winter movements to lower elevations to the north have been blocked by US Interstate 80 since its construction in 1967 (Ward et al. 1976). There has been no documented use of the underpasses under US Interstate 80 by pronghorn in this herd unit. The western portion of the herd unit is intersected by Wyoming Highway 130, which impedes the semi-annual migration of these pronghorn.

POPULATION OBJECTIVE REVIEW

Wyoming Game and Fish Department (WGFD) uses postseason population objectives as a guide for pronghorn management at the herd unit level. The postseason population objective is the desired number of pronghorn remaining in the herd unit after the annual hunting season has been completed. Generally, if the population estimate is above the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will increase harvest and reduce the number of pronghorn toward the population objective. Conversely, if the population estimate is below the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will decrease harvest and increase the number of pronghorn toward the population objective.

An actual count of all pronghorn in a herd unit would be, for all practical purposes, impossible to complete. Therefore, WGFD develops herd unit population estimates using a computer-based population model. Data collected annually through hunter-harvest surveys and preseason pronghorn sex and age classification surveys are incorporated into the population models. The population estimate produced by the computer-based population model is used to determine where the herd unit's pronghorn population is in relation to the established population objective.

Annual population estimates for the Elk Mountain herd unit are currently produced using a computer-based, spreadsheet population model (Morrison 2012). Harvest survey data has been adequate for producing harvest estimates with an acceptable 80% confidence interval. However, due to changes in survey technique in recent years (i.e. changed from aerial to ground surveys), preseason pronghorn sex and age classification survey sample sizes have been less than adequate for producing estimates with acceptable 90% confidence intervals. Additionally, WGFD has conducted 7 pronghorn line transect surveys (Guenzel 2007) to estimate pronghorn density in this herd unit. Density estimates from these line transect surveys were incorporated into the spreadsheet model to improve the population estimate's accuracy.

Postseason pronghorn population objectives for the Elk Mountain herd unit have been adopted and subsequently changed following periodic reviews of both biological and social

considerations. These considerations have included changes in: quantity and quality of habitat, sportsmen desires, and landowner desires/tolerance.

A postseason population objective of 3,000 pronghorn was first established for the Elk Mountain herd unit in the late 1970s. In 1986, the population objective was increased to 5,000 pronghorn because this was considered a more realistic objective since the number of pronghorn consistently observed during surveys was approximately 5,000. In 1996, the population objective was reviewed and maintained at 5,000 pronghorn.

The 2013 postseason population estimate was 2,550 pronghorn. Since 2007, the annual population estimates have declined precipitously in trend (Figure 2). This decline was due in part to several severe winters and severe summer drought. Increased female harvest rates since 2007 also contributed to the decline. These increased female harvest rates were prescribed to assist in reducing pronghorn numbers towards a more appropriate population level in consideration for the severe drought experienced during this period. A recent return to more conservative hunting seasons should increase pronghorn numbers towards the objective.

Figure 2. 1993-2013 Elk Mountain herd unit postseason pronghorn population estimates, Wyoming.

CURRENT MANAGEMENT STRATEGIES BY HUNT AREA

Pronghorn Hunt Area 50 is the only hunt area in the Elk Mountain herd unit and is managed under the recreational management strategy. This strategy directs WGFD to manage harvest opportunity to maintain 30-59 bucks/100 does in the herd unit preseason. Historically, this herd unit has exhibited a very good recruitment rate which tends to lend itself toward being managed under the recreational management strategy.

RECOMMENDED HERD UNIT OBJECTIVE AND MANAGEMENT STRATEGIES BY HUNT AREA

WGFD recommends maintaining the current postseason population objective of 5,000 pronghorn for the Elk Mountain Herd Unit. Continuation of a recreational management strategy is also recommended for this herd unit. We believe this population level can be sustained by the herd unit's currently available pronghorn habitat.

LANDOWNER, AGENCY, AND PUBLIC INVOLVEMENT

WGFD made a concerted effort to provide stakeholders with an opportunity to be involved in the review of the Elk Mountain pronghorn herd unit population objective, and to provide comment on the recommendations.

Landowner Involvement

In February of 2014, a letter describing objective review process and a survey were sent to all landowners (n=53) who owned at least 160 acres in the Elk Mountain herd unit (ATTACHMENT A). We received completed surveys from 10 landowners; for a return rate of 19% (ATTACHMENT B). Ninety percent (90%) of the responding landowners indicated they thought the current population objective was "About Right." Ten percent (10%) of the responding landowners indicated the population objective was, "Too Low," (Figure 3).

Figure 3. Elk Mountain herd unit landowner survey responses to the question, "Do you think the population objective of 5,000 pronghorn is:"

In May of 2014, WGFD sent a postcard to these same landowners describing the recommendation to maintain the population objective at 5,000 pronghorn (ATTACHMENT C). The postcard included an invitation to the landowners to attend upcoming objective recommendation meetings. The postcard also listed an email address where landowners could send their comments electronically. No comments were received from the landowners.

Agency Involvement

In May of 2014, WGFD met with representatives from the US Forest Service (Wendy Haas - Medicine Bow/Routt National Forest); Bureau of Land Management (Heath Cline - Rawlins Field Office); USDA/Natural Resource Conservation Service (Mark Shirley - Saratoga District); and the Saratoga, Encampment, Rawlins Conservation District (Jack Berger and Joe Parsons). WGFD presented a review of the Elk Mountain herd unit population objective and the recommendation. This discussion lasted approximately 2 hours. Agency personnel appeared to be supportive of the recommendation.

Public Involvement

In March of 2014, population objective review meetings were held in conjunction with season-setting public information gathering meetings in Cheyenne, Laramie, and Saratoga. Meeting attendees were asked to fill out sportsperson surveys regarding their attitudes towards current pronghorn numbers and the current population objective (ATTACHMENT D). A total of 110 people attended these meetings and we received 21 completed surveys, for a return rate of 19% (ATTACHMENT E). One Hundred percent (100%) of the survey respondents indicated they thought the current population objective was "About Right," (Figure 4).

Figure 4. Elk Mountain herd unit public objective review meeting attendee survey responses to the question, "Do you think the population objective of 5,000 pronghorn is:"

In May of 2014, population objective recommendation meetings were held in Cheyenne, Laramie, Saratoga, and Wheatland. Meeting attendees were asked to fill out surveys indicating whether or not they supported the proposed population objective recommendation. A total of 21 people attended these 4 meetings and we received 6 completed surveys; for a return rate of 29% (ATTACHMENT F). One-Hundred percent (100%) of the survey respondents indicated they

supported the recommendation to maintain the population objective at 5,000 pronghorn (Figure 5).

Figure 5. Elk Mountain herd unit public objective recommendation meeting attendee survey responses to the statement, “Propose to maintain the population objective of 5,000 pronghorn for the next 5-years.”

17 March 2014

Dear Landowner,

The Wyoming Game and Fish Department (WGFD) is seeking your assistance in the future management of big game wildlife in your area. During the spring of 2014, WGFD will review the herd unit management objectives for several big game herd units such as Platte Valley mule deer, Elk Mountain pronghorn, and Big Creek pronghorn. Enclosed in this letter you will find a short survey for each herd unit your property is located in, and postage-paid return envelope. Please complete the survey questions, provide additional comments if you desire, and mail the survey in the return envelope.

The herd unit management objective is the “benchmark” which WGFD manages big game wildlife towards. For most big game herd units in Wyoming, WGFD manages big game wildlife towards a numeric management objective, usually identified as a specific postseason population estimate.

Many of Wyoming’s big game wildlife rely on habitat located on private lands. Therefore, landowner opinions on herd unit management objectives are important to WGFD. The comments we receive from your completed surveys will be used in part to formulate WGFD recommendations for the future herd unit management objectives. Changes in the herd unit management objective could result in increasing harvest opportunities to decrease big game numbers, or conversely, changes could result in reducing harvest opportunities in order to increase big game numbers.

We also would like to invite you to one of the upcoming public meetings to discuss herd unit management objectives. Locations and dates are listed below:

- Saratoga Town Hall, March 26, 7:30 p.m.
- Laramie Fire Hall #3, March 27, 7:30 p.m.

Thank you for taking the time to share your thoughts and opinions with us. We hope to see you at one of the upcoming meetings. If you have any questions please contact Will Schultz at 307-326-3020. We look forward to receiving your survey and working with you on the future management of Wyoming’s Wildlife.

Sincerely,

Will Schultz
Saratoga Wildlife Biologist
WS/ws

Elk Mountain Pronghorn Herd Unit

Antelope Hunt Area: 50
Management Objective: 5,000 pronghorn
2013 Postseason Population Estimate: 3,800 pronghorn
Last Management Objective Review: 1997

1. How satisfied are you with the current number of pronghorn in the Elk Mountain herd unit (current estimate is 3,800 pronghorn):

☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied

2. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.

☐ There are too many pronghorn in the herd unit
☐ There are too few pronghorn in the herd unit
☐ Other _____

3. Do you think the herd unit management objective of 5,000 pronghorn is:

☐ Too high
☐ Too low
☐ About right

WGFD Public Meeting

Wyoming Game and Fish Department wants to invite you to attend one of the upcoming meetings to discuss herd unit management objective proposals. Earlier this year, we held meetings in these communities asking for your input. Now, we would like to present to you the proposals we developed with the help of your earlier input:

- Recommend increasing the management objective to 800 pronghorn from 600 pronghorn for the Big Creek Pronghorn Herd Unit.
- Recommend maintaining the current management objective of 5,000 pronghorn for the Elk Mountain Pronghorn Herd Unit.
- Recommend decreasing the management objective to 16,000 mule deer from 20,000 mule deer for the Plate Valley Mule Deer Herd Unit.

Your input at these upcoming meetings is important to us! Recommendations, and your input from these meetings, will be presented to the Wyoming Game and Fish Commission in July

For more information please contact:

Saratoga Wildlife Biologist, Will Schultz, 307-326-3020

Pronghorn in the Big Creek herd unit are managed toward a numeric objective of 600. The population was estimated using a spreadsheet model developed in 2012 and updated in 2014. The herd is managed for recreational opportunity. The management objective was reviewed in 2014 and increased to a postseason population estimate of 800 pronghorn (Appendix A).

Herd Unit Issues

Pronghorn damage to alfalfa crops has diminished due to the low number of pronghorn observed in this herd unit. Access is difficult except for on those private lands receiving damage. Recent changes in land use have been observed in this herd unit. Several sections of abandoned wheat fields have been converted into cattle pastures which have been grazed intensively. Development in the Trail Run subdivision is also continuing. In the past these areas provided pronghorn with seasonal habitat and the observed changes in land use appear to be displacing pronghorn into other areas.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of

precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on pronghorn. Mild fall temperatures and lack of persistent snows allowed for pronghorn to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Big Creek herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

The 2014 pre-season ratios were 48 bucks and 51 fawns per 100 does produced from an adequate sample of 537 pronghorn obtained through ground surveys. 2014 fawn ratios had decreased from 62 fawns/100 does in 2013, to 51 fawns/100 does in 2014. This reduction was not expected as pronghorn fawn ratios had increased in adjacent herd units where it was attributed to mild spring weather having been more conducive to fawn survival than in previous years.

Harvest Data

The harvest survey data for the 2014 hunting season indicated a total of 75 pronghorn, 41 bucks, 20 does, and 5 fawns were harvested with an overall harvest success rate of 106%. This high success rate was due to many of the successful hunters possessing both Type 1 and Type 6 licenses and is typical for this herd unit.

Population

In 2014, the CJ, CA spreadsheet model was selected again for the Big Creek herd unit because it produced the lowest AICc score and appeared. The population estimate from this model was also considered to be plausible and representative of field observations. The end of year density estimates developed from Line-Transect density surveys appeared to overestimate actual pronghorn abundance in this herd unit. Small sample sizes and interstate movements of pronghorn for this herd unit may produce bias in Line-Transect survey estimates for this herd unit.

We rated this model as poor, and not biologically defensible in our evaluation. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model (Morrison 2012). The poor rating was primarily due to inadequate sample sizes for preseason classification surveys and the likely violation of an assumption that this is a closed population.

Management Summary

A total of 50 Type 1 and 50 Type 6 licenses were maintained in 2015 for the Big Creek herd unit. This amount of harvest should continue to increase pronghorn numbers toward the management objective. Interstate movement of pronghorn complicates monitoring and subsequent management activities in this herd unit.

2014 BIG CREEK PRONGHORN HERD UNIT AND POPULATION OBJECTIVE REVIEW

Prepared by: Will Schultz, Saratoga Wildlife Biologist

The Big Creek pronghorn herd unit is located in south-central Wyoming (Figure 1). The boundaries for this herd unit consist of the Wyoming-Colorado border on the south, the Encampment River on the west, and the North Platte River on the north and east sides. The Big Creek pronghorn herd unit occurs entirely within Hunt Area 51, and contains 533.8 km² of occupied habitat. The occupied habitat consists primarily of sagebrush grassland and mountain shrub habitat types. Agricultural lands consist of irrigated alfalfa and former wheat fields which are reverting to rangeland. Cattle ranches occupy most of the rangeland in this herd unit. Rural residential development is occurring to the east of the town of Riverside, and in the Baggot Rocks and Skyline areas.

Figure 1. A map of the Big Creek pronghorn herd unit and hunt areas located in south central Wyoming.

Pronghorn in this herd unit tend to migrate north to the North Platte River and west to the Encampment River in fall, and return to the south and east in the spring. This herd is considered an interstate herd connected to the North Park pronghorn herd of Colorado. During severe winters, many of the North Park pronghorn migrate north into the Big Creek herd unit. During milder winters the North Park pronghorn tend to winter in Colorado. Pronghorn from this herd unit may cross the rivers and enter the Iron Springs and Elk Mountain pronghorn herd units, particularly during severe winters.

The interstate nature of this herd makes management difficult. Population estimates and sex and age ratios for this herd fluctuate frequently. Population model simulations have been unreliable. License allocation for the Big Creek herd has been conservative and harvest success has been very good. Damage to standing alfalfa crops has been a sporadic problem in this herd unit. Hunter access is good for private lands sustaining damage, otherwise access can be difficult.

POPULATION OBJECTIVE REVIEW

Wyoming Game and Fish Department (WGFD) uses postseason population objectives as a guide for pronghorn management at the herd unit level. The postseason population objective is the desired number of pronghorn remaining in the herd unit after the annual hunting season has been completed. Generally, if the population estimate is above the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will increase harvest and reduce the number of pronghorn toward the population objective. Conversely, if the population estimate is below the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will decrease harvest and increase the number of pronghorn toward the population objective.

An actual count of all pronghorn in a herd unit would be, for all practical purposes, impossible to complete. Therefore, WGFD develops herd unit population estimates using a computer-based population model. Data collected annually through hunter-harvest surveys and preseason pronghorn sex and age classification surveys are incorporated into the population models. The population estimate produced by the computer-based population model is used to determine where the herd unit's pronghorn population is in relation to the established population objective.

Annual population estimates for the Big Creek herd unit are currently produced using a computer-based, spreadsheet population model (Morrison 2012). Harvest survey data has been adequate for producing harvest estimates with an acceptable 80% confidence interval. However, due to changes in survey technique in recent years (i.e. changed from aerial to ground surveys), preseason pronghorn sex and age classification survey sample sizes have been less than adequate for producing estimates with acceptable 90% confidence intervals. Additionally, WGFD has conducted 7 pronghorn line transect surveys (Guenzel 2007) to estimate pronghorn density in this herd unit. Density estimates from these line transect surveys were incorporated into the spreadsheet model to improve the population estimate's accuracy.

Postseason pronghorn population objectives for the Big Creek herd unit have been adopted and subsequently changed following periodic reviews of both biological and social considerations. These considerations have included changes in: quantity and quality of habitat, sportsmen desires, and landowner desires/tolerance.

A postseason population objective of 100 pronghorn was first established for the Big Creek herd unit in the late 1970s. In 1986, the population objective was increased to 600 pronghorn. This was considered a more realistic objective since the number of pronghorn consistently observed during surveys was approximately 600. In 1996, the population objective was reviewed and maintained at 600 pronghorn.

The 2013 postseason population estimate was 760 pronghorn. Since 1993, annual population estimates have generally declined in trend (Figure 2). The interstate nature of pronghorn in this herd unit has made monitoring with certainty difficult. Most annual postseason population estimates have been greater than the current population objective of 600 pronghorn.

Figure 2. 1993-2013 Big Creek herd unit postseason pronghorn population estimates, Wyoming.

CURRENT MANAGEMENT STRATEGIES BY HUNT AREA

Pronghorn Hunt Area 51 is the only hunt area in the Big Creek herd unit and is managed under the recreational management strategy. This strategy directs WGFD to manage harvest opportunity to maintain 30-59 bucks/100 does in the herd unit preseason. Historically, this herd unit's harvest rates have been conservative and buck ratios were allowed to approach or exceed the upper limit of the recreational management strategy parameter. The interstate nature of these pronghorn and the limited access for hunting have made it challenging to offer more liberal buck harvest opportunity, with any certainty of maintaining a satisfactory hunting experience for the hunter.

RECOMMENDED HERD UNIT OBJECTIVE AND MANAGEMENT STRATEGIES BY HUNT AREA

WGFD recommends increasing the current postseason population objective from 600 pronghorn to 800 pronghorn for the Big Creek Herd Unit. The proposed management objective provides for a more realistic goal to manage pronghorn numbers towards in this herd unit. This increase is based on the differences in population estimation between the discontinued POP-II population model and the recently adopted spreadsheet model. Continuation of a recreational management strategy is also recommended for this herd unit. We believe this population level can be sustained by the herd unit's currently available pronghorn habitat.

LANDOWNER, AGENCY, AND PUBLIC INVOLVEMENT

WGFD made a concerted effort to provide stakeholders with an opportunity to be involved in the review of the Big Creek pronghorn herd unit population objective, and to provide comment on the recommendations.

Landowner Involvement

In February of 2014, a letter describing objective review process and a survey were sent to all landowners (n=35) who owned at least 160 acres in the Big Creek herd unit (ATTACHMENT A). We received completed surveys from 10 landowners; for a return rate of 29% (ATTACHMENT B). Seventy percent (70%) of the responding landowners indicated they thought the current population objective was "About Right," (Figure 3). Ten percent (10%) of the responding landowners indicated the population objective was, "Too Low."

Figure 3. Big Creek herd unit landowner survey responses to the question, "Do you think the population objective of 600 pronghorn is:"

In May of 2014, WGFD sent a postcard to these same landowners describing the recommendation to increase the population objective from 600 pronghorn to 800 pronghorn (ATTACHMENT C). The postcard included an invitation to the landowners to attend upcoming objective recommendation meetings. The postcard also listed an email address where

landowners could send their comments electronically. No comments were received from the landowners.

Agency Involvement

In May of 2014, WGFD met with representatives from the US Forest Service (Wendy Haas - Medicine Bow/Routt National Forest); Bureau of Land Management (Heath Cline - Rawlins Field Office); USDA/Natural Resource Conservation Service (Mark Shirley - Saratoga District); and the Saratoga, Encampment, Rawlins Conservation District (Jack Berger and Joe Parsons). WGFD presented a review of the Big Creek herd unit population objective and the recommendation. This discussion lasted approximately 2 hours. Agency personnel appeared to be supportive of the recommendation.

Public Involvement

In March of 2014, population objective review meetings were held in conjunction with season-setting public information gathering meetings in Cheyenne, Laramie, and Saratoga. Meeting attendees were asked to fill out sportsperson surveys regarding their attitudes towards current pronghorn numbers and the current population objective (ATTACHMENT D). A total of 110 people attended these meetings and we received 21 completed surveys, for a return rate of 19% (ATTACHMENT E). Fifty percent (50%) of the survey respondents indicated they thought the current population objective was “About Right.” Fifty percent (50%) of the survey respondents indicated the population objective was, “Too Low” (Figure 4).

Figure 4. Big Creek herd unit public objective review meeting attendee survey responses to the question, “Do you think the population objective of 600 pronghorn is:”

In May of 2014, population objective recommendation meetings were held in Cheyenne, Laramie, Saratoga, and Wheatland. Meeting attendees were asked to fill out surveys indicating whether or not they supported the proposed population objective recommendation. A total of 21 people attended these 4 meetings and we received 6 completed surveys; for a return rate of 29% (ATTACHMENT F). Sixty-seven percent (67%) of the survey respondents indicated they supported the recommendation to increase the population objective from 600 pronghorn to 800 pronghorn (Figure 5.).

Figure 5. Big Creek herd unit public objective recommendation meeting attendee survey responses to the statement, “Propose to increase the population objective from 600 to 800 pronghorn for the next 5-years.”

17 March 2014

Dear Landowner,

The Wyoming Game and Fish Department (WGFD) is seeking your assistance in the future management of big game wildlife in your area. During the spring of 2014, WGFD will review the herd unit management objectives for several big game herd units such as Platte Valley mule deer, Elk Mountain pronghorn, and Big Creek pronghorn. Enclosed in this letter you will find a short survey for each herd unit your property is located in, and postage-paid return envelope. Please complete the survey questions, provide additional comments if you desire, and mail the survey in the return envelope.

The herd unit management objective is the “benchmark” which WGFD manages big game wildlife towards. For most big game herd units in Wyoming, WGFD manages big game wildlife towards a numeric management objective, usually identified as a specific postseason population estimate.

Many of Wyoming’s big game wildlife rely on habitat located on private lands. Therefore, landowner opinions on herd unit management objectives are important to WGFD. The comments we receive from your completed surveys will be used in part to formulate WGFD recommendations for the future herd unit management objectives. Changes in the herd unit management objective could result in increasing harvest opportunities to decrease big game numbers, or conversely, changes could result in reducing harvest opportunities in order to increase big game numbers.

We also would like to invite you to one of the upcoming public meetings to discuss herd unit management objectives. Locations and dates are listed below:

- Saratoga Town Hall, March 26, 7:30 p.m.
- Laramie Fire Hall #3, March 27, 7:30 p.m.

Thank you for taking the time to share your thoughts and opinions with us. We hope to see you at one of the upcoming meetings. If you have any questions please contact Will Schultz at 307-326-3020. We look forward to receiving your survey and working with you on the future management of Wyoming’s Wildlife.

Sincerely,

Will Schultz
Saratoga Wildlife Biologist
WS/ws

Big Creek Pronghorn Herd Unit

Antelope Hunt Area: 51
Management Objective: 600 pronghorn
2013 Postseason Population Estimate: 800 pronghorn
Last Management Objective Review: 1997

1. How satisfied are you with the current number of pronghorn in the Big Creek herd unit (current estimate is 800 pronghorn):
☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied
2. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.
☐ There are too many pronghorn in the herd unit
☐ There are too few pronghorn in the herd unit
☐ Other _____
3. Do you think the herd unit management objective of 600 pronghorn is:
☐ Too high
☐ Too low
☐ About right

Somewhat Satisfied	6	60%
Somewhat Dissatisfied	1	10%
Very Dissatisfied	0	0%

If you answered somewhat dissatisfied or very dissatisfied, please indicate why

There are too many pronghorn in the herd unit	1	50%
There are too few pronghorn in the herd unit	1	50%
Other	0	0%

Do you think the herd unit management objective of 600 pronghorn is

Comments

What are the migration patterns for this herd? Does this herd winter in the same area as mule deer and/or Elk? The latter two should be the priority. **I feel the pronghorn in this area are still trying to recover from the drought followed by several hard winters. If the estimate of 800 pronghorn post season 2013 is correct then the herd management objective is WAY TO LOW. On a daily basis I see very few pronghorn. Especially compared to 8-10 years ago. The pronghorn in area 51 are struggling!** **Since this herd spends a great deal of time in CO and weather determining if or when they migrate, I don't believe we have anywhere near 800 antelope during hunting season. We need to increase resident herd and not worry about CO. antelope. One late season harvests some of CO antelope.** **Again why aren't management objective reviews done more often? Looks like proper big game management is being ignored.**

(Hunt Area 51)

Elk Mountain Pronghorn
(Hunt Area 50)

Platte Valley Mule Deer
(Hunt Areas 78,79,80,81,83,161)

WGFD Public Meeting

Wyoming Game and Fish Department wants to invite you to attend one of the upcoming meetings to discuss herd unit management objective proposals. Earlier this year, we held meetings in these communities asking for your input. Now, we would like to present to you the proposals we developed with the help of your earlier input:

- Recommend increasing the management objective to 800 pronghorn from 600 pronghorn for the Big Creek Pronghorn Herd Unit.
- Recommend maintaining the current management objective of 5,000 pronghorn for the Elk Mountain Pronghorn Herd Unit.
- Recommend decreasing the management objective to 16,000 mule deer from 20,000 mule deer for the Plate Valley Mule Deer Herd Unit.

Your input at these upcoming meetings is important to us! Recommendations, and your input from these meetings, will be presented to the Wyoming Game and Fish Commission in July

For more information please contact:

Saratoga Wildlife Biologist, Will Schultz, 307-326-3020

Sportsperson Survey

Platte Valley Mule Deer Herd Unit

1. Please circle the hunt area where you spend the majority of your time hunting mule deer:
Hunt Area 78 79 80 81 83 161 elsewhere
2. How satisfied are you with the current number of mule deer wintering in the Platte Valley herd unit (current estimate is 8,800 mule deer):
☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied
3. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.
☐ There are too many mule deer in the herd unit
☐ There are too few mule deer in the herd unit
☐ Other _____
4. Do you think the herd unit management objective of 20,000 mule deer is:
☐ Too high
☐ Too low
☐ About right
5. Would you support combining Hunt Area 80 and Hunt Area 83 into one hunt area for future hunting seasons?
☐ Yes
☐ No
☐ I am neither for or against
6. Would you support dividing Hunt Area 161 along the Big Ditch? This would result in the southern portion of Hunt Area 161 being combined into Hunt Area 79 and the northern portion of Hunt Area 161 being combined into Hunt Area 70, for future hunting seasons.
☐ Yes
☐ No
☐ I am neither for or against

Elk Mountain and Big Creek Pronghorn Herd Unit

7. Please circle the hunt area where you spend the majority of your time hunting pronghorn:
Hunt Areas 50 51 elsewhere
8. How satisfied are you with the current number of pronghorn in the **Elk Mountain herd unit** (current estimate is 3,800 pronghorn):
☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied

SURVEY IS CONTINUED ON BACK

9. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.

- ☐ There are too many pronghorn in the herd unit
- ☐ There are too few pronghorn in the herd unit
- ☐ Other _____

10. Do you think the herd unit management objective of 5,000 pronghorn in the **Elk Mountain herd unit** is:

- ☐ Too high
- ☐ Too low
- ☐ About right

Herd Unit Management Objective Proposal Meeting
Saratoga Town Hall – 6:00 PM, 22 May 2014

Platte Valley Mule Deer

Current population estimate = 8,800 mule deer

Propose to decrease the management objective from 20,000 to 16,000 mule deer for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Elk Mountain Pronghorn

Current population estimate = 3,800 pronghorn

Propose to maintain the management objective of 5,000 pronghorn for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Big Creek Pronghorn

Current population estimate = 800 pronghorn

Propose to increase the management objective from 600 to 800 pronghorn for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Management Evaluation

Current Postseason Population Management Objective: 350

2014 Postseason Population Estimate: ~ 75

2015 Proposed Postseason Population Estimate: ~ 75

Management Strategy: Special

The management objective for the Douglas creek Bighorn Sheep Herd Unit is a post-season population objective of 350 bighorn sheep. The management strategy is special management. The herd objective and management strategy were last revised in 1986 and will be reviewed in 2016.

Herd unit Issues

The Douglas Creek Herd Unit is located primarily in the Savage Run and Platte River Wilderness areas in the Snowy Range Mountains on the Medicine Bow National Forest. The herd is under special management guidelines which require the mean age of harvested rams to be between 6-and 8 years old. This direction was taken to provide trophy opportunity to the public and allow this herd to grow. Pine Beetles have dramatically changed the landscape in the Medicine Bow National Forest where a large percentage of mature pines have died and starting to fall over. The impacts from the beetle kill are unclear but could improve sheep habitat as the forest becomes more open. Area 18 was closed from 2004 through 2007 and then again in 2009, 2011, and 2013 because this population has remained below desired levels. Hunt Area 18 will be closed again in 2015.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

We have very little data on this population. The general public provides a few reports during the summer and hunting seasons. Our field personnel make some effort to document the status of segments of the herd during other big game surveys and an annual winter ground survey. Past observation data consistently documents low post-weaning lamb survival. Poor habitat conditions, the lack of well-defined seasonal migrations, and perhaps lingering effects of Pasteurellosis or some other disease may be stagnating this population. We classified 40 sheep in February, with a lamb to ewe ratio of 64:100, which is down from the 2013 estimate of 74:100 but much higher than past counts. 50 sheep were seen in October in the same area but were not

classified. An area 18 hunter observed a bachelor herd of 12 plus rams west of the Platte River, and 15 sheep were observed by 230 at the state line.

Harvest Data

We offered 2 resident licenses in 2014 and each hunter harvest a ram; one ram was 11 years old and the other was 2. One hunter saw 50 sheep on his hunt which is comparable to what field staff saw this summer.

Population

Data is not adequate for developing a reasonable population model. We are unable to collect the data needed to reliably estimate the population size of this sheep herd.

Management Strategy

The season closure will provide an additional year to allow the available rams an opportunity to attain the minimum 6 year old age class specified by the special management guidelines.

Management Evaluation

Current Management Objective:

- 1) 5-year running average of $\geq 75\%$ hunter success- 89%
- 2) 5-year running average age of harvested rams between 6 and 8 years of age 2010-2014 Average Age: 6 years old
- 3) Documented occurrence of adult rams in the population

Management Strategy: Recreational

Herd Unit Issues

The management objective for the Laramie Peak Bighorn Sheep herd was a post-season population objective of 500 wild sheep. The management strategy is recreational management. The objective and strategy were last revised in 1978. The population objective was reviewed during the winter/spring of 2014. Based on department staff, landowner, and public comments the following population management alternative objectives were approved by the WGFD Commission:

- 1) 5-year running average of $\geq 75\%$ hunter success
- 2) 5-year running average age of harvested rams between 6 and 8 years of age
- 3) Documented occurrence of adult rams in the population

The Laramie Peak Herd Unit is comprised of 70% private land. The southern portion (south of WY Hwy 34) is over 90% private land. Hunters can expect to pay a trespass/trophy or outfitter fee to hunt on private land. There are two state sections that hunters can access that hold sheep throughout the season and have produced adult rams in past hunting seasons. A portion of occupied sheep habitat was within the 2012 Arapahoe fire that burned over 98,000 acres. This affected sheep distribution post-fire, but above average summer/fall precipitation in 2013 and spring precipitation in 2014 resulted in increased vegetation production for pre-winter diets and early spring green up that will benefit parturition areas for pregnant ewes. The fire will have long-term benefits for wild sheep, but initially there has been a flush of noxious weeds (e.g. cheatgrass, Canada thistle) that land managers will need to address. A majority of wild sheep are harvested within the northern portion of the herd unit. The Laramie Peak Wildlife Habitat Management Unit provides essential habitat to 200 plus sheep, and provides some of the only

public hunting access within this herd. In 2007 forty-two sheep were released in this area from the Perma-Paradise Herd in Montana. These sheep have thrived and improved the overall genetics and health of the existing herd.

During the winter of 2014/15 the WGFD tried to gather biological samples for disease surveillance, with a target goal of 150 bighorn sheep across Wyoming through the use of drop nets, free-darting, and aerial captures. The goal of this effort is to obtain information on each herd and its overall health. Some animals will be fitted with GPS radio-collars to increase our understanding of movements and habitat use. The goal for the Laramie Peak Herd Unit was to collect samples from 15 wild sheep between Sybille Canyon and Iron Mountain. A drop net was set up on Iron Mountain, unfortunately the bighorn sheep did not come to the bait under the net. Grants through the Governor's Big Game License Coalition and the Wyoming Wild Sheep Foundation will be submitted for aerial capture efforts during the 2015/15 winter to obtain the necessary sample size of 15.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the Laramie Peak Bighorn Sheep Herd Unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on bighorn sheep. Mild fall temperatures and lack of persistent snows allowed for bighorn sheep to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Laramie Peak Bighorn Sheep Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in Spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain

mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In Spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

In 2014 there were seven bighorn sheep harvested in with an average of 6 years old and hunters experienced a 88% success rate. The five-year age average is 7 years and the five-year running success average is 89%, which met the two alternative objective criteria.

Since 1964 there have been a total of 228 wild sheep released from two herd sources: Whiskey Mountain in Wyoming and Perma-Paradise in Montana (Table 1). These transplants have helped to supplement the herd and improve overall herd health.

Table 1. Transplant release data for the Laramie Peak Bighorn Sheep Herd.

Year	Number	Release Location	Source Herd
1964	40	North Laramie River Canyon	Whiskey Mountain Herd
1965	36	Labonte Canyon	Whiskey Mountain Herd
1966	21	Labonte Canyon	Whiskey Mountain Herd
1973	42	Duck Creek Canyon	Whiskey Mountain Herd
1982	27	Marshall	Whiskey Mountain Herd
1989	20	Marshall	Whiskey Mountain Herd
2007	42	Hay Canyon	Perma-Paradise- MT
Total	228		

Lamb recruitment continues to improve compared to ratios prior to the 2007 release. There was a total of 81 wild sheep classified in 2014 with an above average ratio of 55 lambs:100 ewes. Ram ratios were highly skewed with more rams observed than ewes. Based on surveys there is a well represented number for each age class. Several 8+ old rams were observed in the Duck Creek sub-herd.

In 2014, 7 out of 8 sheep licenses were successful. One license will carryover to 2015 due to a medical hardship. Four sheep were harvested from the Duck Creek sub-herd and three from the Sybille Canyon sub-herd.

Harvest Data

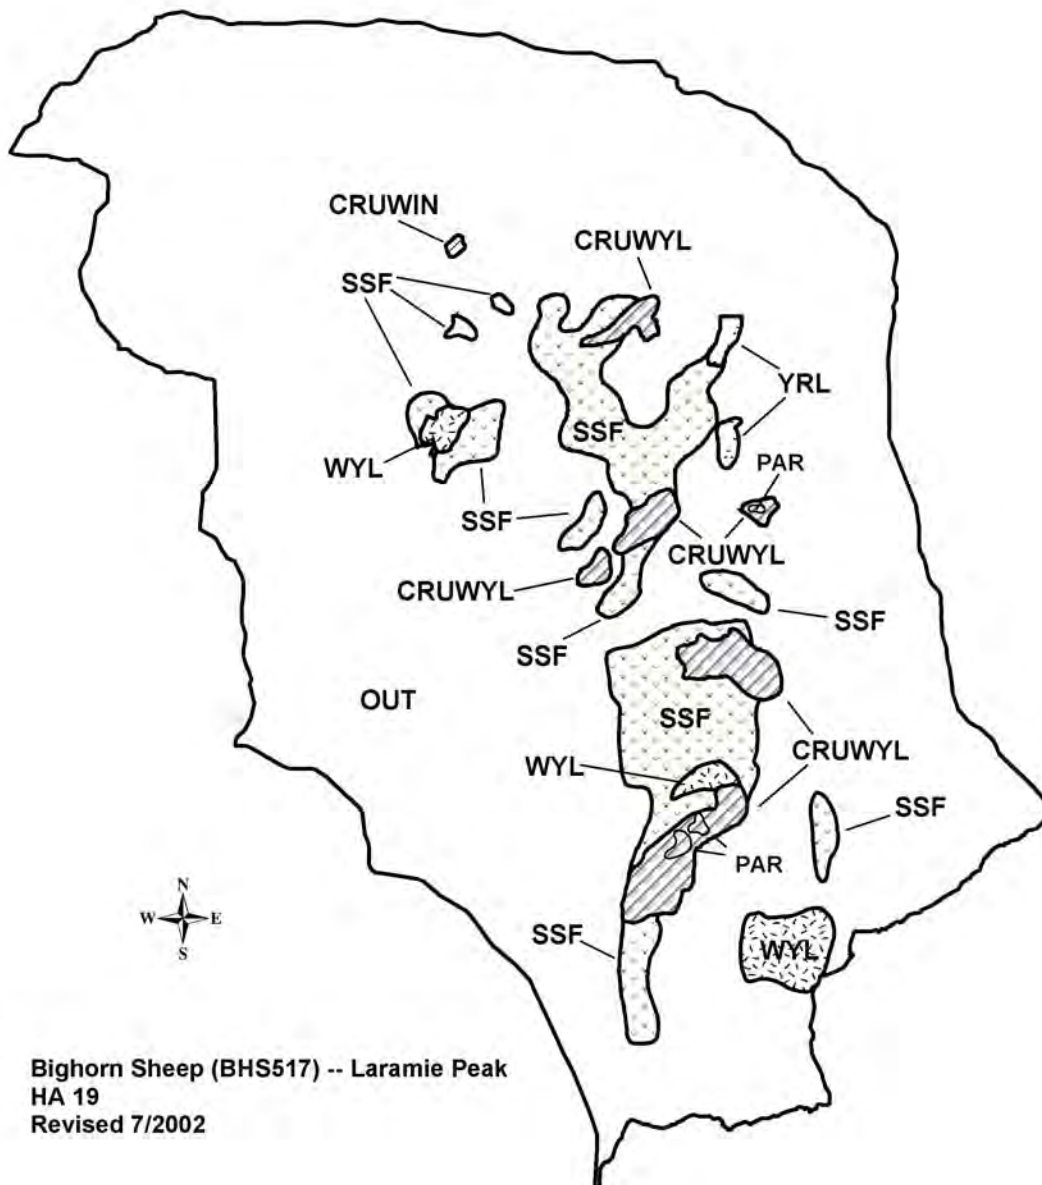

Success has reached $\geq 75\%$ five out of the past five years. This last year active license hunters harvested 7 out of 8 rams, with a success rate of 88%. Hunters who pre-scout or hire an outfitter typically harvest their ram within 3-5 days. This year the average hunter effort was 10 days, which was lower than the five-year average of 13 days per harvest. Hunters that chose to not use an outfitter spend more time scouting and hunting. There is limited public land within occupied wild sheep habitat. Overcrowding is an issue that results in pushing bighorn sheep onto private land, where there is no access. To maintain high harvest success no more than 8 licenses are issued. In the past when the quota increased to 12, success decreased drastically.

The Laramie Peak bighorn sheep season has been September 1-October 31 for the past 24 years. Prior to that, the season ran from September 1- October 14. The increased season length appears to provide adequate opportunity to harvest a ram, given this is typically a once in a lifetime license.

In 2012 there were several fires that burned within bighorn sheep occupied habitat. The Arapahoe, Cow Camp, and Russell's Camp fires burned over 112,000 acres, with the Arapahoe fire being the largest (98,000 acres). Throughout the area there is observed recovery in vegetation. Photo points have been established throughout the fire to document plant succession. Perennial forbs and grasses along with aspen have re-established post-fire.

There is not a reliable working model for this herd unit due to limited population data collected on an annual basis.

For the 2014 season, 8 licenses will be offered for any ram along with 1 carryover license for a total of 9. Hunters should have a high probability of harvesting a mature ram. There is some concern with nine hunters going to the field that success will be compromised. To improve harvest success hunters will need to put more time into scouting and hunting if they are accessing public lands.

Management Evaluation

Current Management Objective: 200 (160-240)

Management Strategy: Special

2013 Postseason Population Estimate: NA

2014 Proposed Postseason Population Estimate: NA

Bighorn sheep in the Encampment River herd unit are managed toward a numeric objective of 200. A population model has not been constructed for the herd unit. The herd is managed under the bighorn sheep special management strategy. The objective was last reviewed in 1987.

Herd Unit Issues

Bighorn sheep numbers in this herd unit appeared to peak in the late 1970s, not long after reintroduction efforts. Bighorn sheep numbers have been in decline since the early 1980s. The lack of a rebound in numbers has been attributed to decadent habitat. Domestic sheep in grazing on the west slope of the Sierra Madres also poses a disease concern for managers. The population is now at such a low number it is assumed natural recovery is not possible. Limited harvest opportunities have been offered in past years, in combination with the Douglas Creek bighorn sheep herd unit.

In 2013, the State of Wyoming, and thus the Wyoming Game and Fish Department, intervened on behalf of the U.S. Forest Service, in the U.S. District Court case, BIODIVERSITY CONSERVATION ALLIANCE vs. BUTCH BLAZER, et al. This case continues to await a ruling, and may affect future management of bighorn sheep in this herd unit.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on bighorn sheep. Mild fall temperatures and lack of persistent snows allowed for bighorn sheep to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Encampment River herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunk brush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

Adequate classification data for this herd has been difficult to collect. 2014 postseason classification observations were obtained while conducting mule deer and elk survey

from a helicopter in December of 2014. The classification results were 3 adult rams, 1 yearling ram, 17 ewes, and 7 lambs. Past postseason classification efforts generally have located a greater number of ewes and lambs than what was observed in 2014. We received several reports of a group of 20+ ewes and lambs in the North Fork area during the fall of 2014 but unable to collect classification information for this group. Based on the trend of classification data and casual observations, a reasonable estimate of 25-50 bighorn sheep should be considered for this herd unit.

Population

A population model has not been constructed for this herd unit due to limited classification and no annual survival information. A review of the management objective, currently at 200 bighorn sheep, will be evaluated within the next 2-years.

Harvest Data

Two (2) licenses were offered in 2014 valid in both Hunt Area 18 and 21. The hunters each harvested a bighorn ram in Hunt Area 18. Therefore, no harvest occurred in the Encampment River herd unit (Hunt Area 21).

Management Summary

The hunting season will be closed in 2015. We will evaluate offering a harvest opportunity for the combination of Hunt Areas 18 and 21 again in 2016.

MANAGEMENT EVALUATION

Current Postseason Population Management Objective: 1,800 (1,400-2,100)

Management Strategy: Recreational

2014 Postseason population Estimate: ~ 3,100

2015 Proposed Postseason Population Estimate: ~ 2,700

2014 Hunter Satisfaction: 68% Satisfied, Neutral 18%, Dissatisfied 14%

The management objective for the Iron Mountain Elk herd unit is a post-season population objective of 1,800 elk. The management strategy is recreational management which requires maintaining a post hunt bull ratio of 15 to 29:100 cows. The objective and management strategy were last revised in 2013.

Herd Unit Issues

The Iron Mountain Elk herd unit includes hunt area 6 (combined hunt areas 5 and 6 for 2014 season) which is composed of mostly private lands except for the Pole Mountain National Forest segment which is managed under a limited quota license to maintain hunt quality. Urban sprawl and nontraditional landowners are increasing in the herd unit. The 2014 post-season population estimate was 3,100 with the population trending downward from a high of 5,100 in 2011.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Field Data

A total of 848 elk were classified which exceeded the estimated classification objective of 670. 2014 calf ratios were comparable to 2013 (49:100 cows) at 48: 100 cows. Bull ratios declined from 29:100 cows in 2013 to 22:100 cows in 2014 which may be a factor of harvest, but could also be due to missing some of the bachelor groups during our classifications. With fewer hunters in the field that are unfamiliar with the area we saw hunter success in 2014 increase by 10%, and hunter effort decreased by 1 day. After switching from limited quota to general licenses hunter numbers have been on a steady decline from a high of 2,480 hunters in 2012 to 1,600 in 2014. We expect this trend to continue as the public realizes how difficult it is to find access.

Harvest Data

The Iron Mountain HMAP was not implemented during the 2014 season, but harvest in 2014 was comparable to 2013 with a total of 750 elk harvested. It seems that more landowners are allowing hunters to harvest cow elk and that is maintaining harvest levels in the herd at an appropriate level to decrease the population. Both the type 1 and type 4 license success increased and are providing opportunity on the only national forest land within the herd unit. Both license types remain very popular with the public with drawing odds less than 10% for residents and nonresidents needing 5 or more preference point to draw the type 1 license.

Population

This is the second year that we have had enough data to run a model. The constant juvenile and adult survival model had an AIC score of 362 and a best Fit of 372. It did not have the lowest AIC score but predicted a more reasonable population estimate to what field staff believes exists on the ground. This model predicts the population declining from a high of 5,900 in 2011 to the current population estimate of 3,100 in 2014. This model is ranked poor for a variety of reasons including: little data available; ratio data, if available, considered highly biased because of poor sample sizes or an inability to survey the entire area; herd unit closure issues apparent; results not biologically defensible.

Management Summary

The 2014 season structure went well and maintained the 2013 harvest of 750 without an HMAP program. The hunting season is status quo for the 2015 season structure. This herd unit continues to be a concern with landowners due to large wintering herds of elk, sometimes exceeding 800. At the same time most all of the landowners in the herd unit outfit elk hunters to some degree on their property and bull quality and quantity is a concern. If we harvest a minimum of 650 elk, we will continue to reduce the population towards the objective. The Sherman Hill HMA, located near the Colorado boarder, was added in 2013 and provides some access in the southern part of the herd unit, but harvest is minimal.

Management Evaluation

Current Management Objective: 6,000 (4,800 – 7,200)

Management Strategy: Recreational

2014 Postseason Population Estimate: 8,000

2015 Proposed Postseason Population Estimate: 8,000

2014 Hunter Satisfaction: 65% Satisfied, 20% Neutral, 15% Dissatisfied

Elk in The Snowy Range herd unit are managed toward a numeric objective of 6,000. The population was estimated using a spreadsheet models developed in 2012 and updated in 2014. The herd is managed for recreation opportunity. The objective was last reviewed in 2013.

Herd Unit Issues

The Snowy Range herd unit covers a large portion of south central Wyoming. Issues here include development in the form of energy, agricultural, residential, invasive and noxious plants, forestry and range management, and travel management in important elk habitat.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. Neither significant prolonged periods of extreme heat or cold temperatures were observed nor was extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on elk. Mild fall temperatures and lack of persistent snows

allowed for elk to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Snowy Range herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunk brush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently have not heavily influenced population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Turnover in personnel, changes in individual job responsibilities of employees, and evolving WGFD agency priorities have resulted in some issues with consistent habitat data collection and interpretation of data. Some transects, years after their initial establishment, have been identified as being in “non-representative” locations. Site selection was often influenced by terrain and/or land ownership status (i.e. public access). Changing land uses (wind turbines, roads, fence construction, other developments, etc.) have influenced habitat use by wildlife in some locations, and in some instances have resulted in major shifts in animal usage of the area being monitored. Department personnel are currently evaluating shrub transects and the types of information being collected, and will be looking for ways to improve efficiency of data collection, types of data being collected, and refining criteria for site selection for future transects. This may result in changing habitat monitoring protocols to improve the quality and quantity of data being gathered. These potential changes will hopefully result in improved validity of

habitat information being gathered, and may prove to be a useful tool in population management of wild ungulates.

Field Data

In 2014, we classified elk from a helicopter in conjunction with local mule deer classifications. A postseason classification sample of 2,816 elk produced ratios of 25 bulls and 50 calves per 100 cows in this herd unit (Figure 1). The high calf ratio was attributed to the previous mild winter and timely summer precipitation which enhanced calf and survival. A comparison of the trend in bull ratios between general season hunt areas and limited quota hunt areas in the Snowy Range herd unit demonstrated the difference in ratios between the 2 hunting season strategies (Figure 2). Limited quota area bull ratios were generally higher in trend than in general hunt areas. The trend in general hunt area ratios has become stable and within the recreational management strategy parameters.

Figure 1. 2005-2014 Bull and calf ratios per 100 cows from the Snowy Range Elk Herd Unit, Wyoming.

Figure 2. 2000-2014 Bull ratios per 100 cows from limited quota (8, 11, 114, 125) and general season (9, 10, 12, 110) Hunt Areas in the Snowy Range Elk Herd Unit, Wyoming.

Harvest Data

The 2014 preliminary harvest survey data indicated 6,200 (same as 2013) active licensed hunters harvested 2,200 (15% decrease from 2013), with a total harvest success rate of 35% (6% decrease from 2013). Branch antlered bulls accounted for 90% of the male harvest in 2014 and 44% of the overall harvest. The spikes excluded seasons in areas 12 and 110 did result in lower spike harvest rates in those hunts when compared to previous year's harvest rates. The proportion of spikes in the male harvest for the entire herd unit declined from 9% in 2013 to 5% in 2014. Postseason spike ratios in hunt areas 12 and 110 improved with the general season limitation in 2014. Antlerless elk accounted for 56% of the total 2014 elk harvest. Overall, harvest rates under the current liberal hunting season structure continue to be maintained at a very acceptable level.

Population

In 2014, we switched from the SCJ, SCA spreadsheet model to the CJ, CA model to simulate Snowy Range herd unit population dynamics. The other 2014 models either ceased to run due to predicting bull harvest exceeding the number estimated to be available; or was not biologically realistic (i.e. 50,000 elk in 1993). This switch in models and the relatively high 2014 calf ratio increased the 2014 postseason estimate by approximately 2,000 elk over what we were predicting in 2013. A decreasing trend in the annual estimate was retained in the CJ, CA and considered to be consistent with the observations by field managers. Without other information such as an independent abundance estimate or historical survival data to incorporate into the model accuracy of estimates will continue to be unknown. We considered the 2014 postseason estimate produced by the CJ, CA spreadsheet model to be plausible.

We rated this model as fair, and biologically defensible in our evaluation. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model (Morrison 2012).

Management Summary

The hunting seasons in the Snowy Range Herd Unit continue to provide opportunities to reduce the overall elk population. Elk numbers appear to be declining towards the management objective and we may need to consider reducing antlerless harvest rates in the not so distant future. In addition to the Hunt Areas 12 and 110, spikes excluded limitations were added to the Hunt Area 9 and 10 general season limitation to assist in maintaining future branch antlered bull ratios, which had been in decline.

A Type 9 archery only season was added to Hunt Area 11 in order to provide additional hunting opportunity. This license type was supported by the results of a survey which gauged the attitudes of hunters who had previously applied to hunt in Hunt Area 11 (APPENDIX I). The survey indicated hunters who supported the addition of a Type 9 license supported implementing this season as a choose your weapon season; where only Type 9 hunters would be allowed to hunt in September and Type 1 and Type 4 licensed hunters would only be able to hunt during the rifle season in October. However, Type 1 and Type 4 licensed hunters will also be allowed an opportunity to hunt September 15 – September 30 with a Special Archery permit.

2014 Elk Hunt Area 11 hunter attitude survey regarding Type 9 archery only elk licenses

Conducted by: Corey Class, Laramie Region Wildlife Management Coordinator

Survey Summary

In late summer of 2014 the Wyoming Game and Fish Department developed and sent out an invitation to participate in a Type 9 (archery only) elk hunter survey online to 326 randomly selected Type 1 and 4 elk hunters from Hunt Area 11. The survey process was initiated due to a high demand for type 9 hunting opportunities for elk demonstrated during the previous year's season setting process. The pool of hunters included all hunters who applied for Type 1 or Type 4 licenses over the past 3 years. A power analysis was conducted to determine how many surveys would need to be obtained using an assumed response rate of 30%. This assumption proved to be optimistic, with only 51 (16%) people responding to the survey. Overall, respondents desired a Type 9 elk hunt in hunt area 11, and they preferred the Type 9 be exclusive to archery hunters only, removing the traditional Type 1 special archery season for Type 1 and Type 4 license holders.

Survey Question Results

1. What weapon do you prefer to use when hunting in elk Hunt Area 11?

Archery	33
Firearm	17

2. Have you ever archery hunted elk in Hunt Area 11?

Yes 24

No 25

3. For Elk Hunt Area 11, would you support the addition of a Type 9 license (archery only) hunting opportunity?

Neutral 2

Somewhat Support 3

Strongly Support 30

Somewhat Oppose 6

Strongly Oppose 9

4. If you strongly support or somewhat support a Type 9 (archery only) hunting opportunity, what format would you prefer?

- Choose your weapon - Only Type 9 hunters can hunt the archery season, which would mean a "choose your weapon season" while Type 1 hunters would only be able to hunt the rifle season.
- Split - Only Type 9 hunters can hunt the first two weeks of September, but both Type 9 and Type 1 hunters can hunt the last two weeks of September.
- Share - Type 9 hunters and Type 1 hunters hunt archery season together.

Choose your weapon	27
Split	1
Share	6

5. Have you applied for Type 9 (archery only) elk licenses before?

Yes 6 (Hunt Areas 32, 34, Bighorns)

No 45

6. If you support Type 9 (archery only) hunting opportunities in Elk Hunt Area 11, Why?

It may increase my odds of drawing this hunt 25

It may improve the quality of the hunting experience 18

It will reduce hunter crowding 16

Other (see raw data) 7

7. Would you continue to apply for a Type 1 Elk License in Hunt Area 11 if the special archery hunt was removed and became a Type 9 only hunt?

Yes 26

No 25

FIGURES

Comments:
 The CA, CA model was selected because it produced the only biologically plausible model which continued to function through 2015. This is the simplest model but may overestimate the population. However, without other information (e.g. an independent population estimate or survival data) for comparison it is difficult to determine which of these 4 models produced the most accurate estimate. Management Evaluation

Current Management Objective: 800 (640 - 960)

Management Strategy: Recreational

2014 Postseason Population Estimate: 700

2015 Proposed Postseason Population Estimate: 400

2014 Hunter Satisfaction: 75% Satisfied, 15% Neutral, 10% Dissatisfied

Elk in the Shirley Mountain herd unit are managed toward a numeric objective of 800. The population was estimated using a spreadsheet model developed in 2012 and updated in 2014. The herd is managed for recreation opportunity. The objective was last reviewed in 1997 and planned for review in 2015.

Herd Unit Issues

Wind energy developments are a relatively new land use in this herd unit. There are currently 2 wind farms in this herd unit and there is interest in developing more wind farms. Our ability to manage elk numbers through harvest is difficult because a large portion of the elk habitat in this herd unit is owned by one landowner who provides a very limited amount of access. Elk damage in this herd unit is minimal. Interchange of elk with adjacent herd units may compromise the closed population assumption for this herd unit. Annual population monitoring efforts and results have been highly variable due to no annual allocation of flight budget resources.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on elk. Mild fall temperatures and lack of persistent snows allowed for elk to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Shirley Mountain herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunk brush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago.

Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently have not heavily influenced population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Field Data

Postseason classification surveys were conducted from the ground in January of 2015. The 2014 postseason ratios were 21 bulls and 43 calves/100 cows, from a sample size of 482 elk. This sample is thought to have under sampled the bull segment of the population. The trend from past classifications inferred this herd unit was still above the recreational management strategy maximum for bull ratios (Figure 1). The collection of classification data has varied annually in methodology primarily due to no dedicated flight budget for this herd.

Figure 1. Wyoming 2005-2014 Shirley Mountain Elk Herd Unit bull and calf ratio trend.

Harvest Data

Preliminary elk harvest survey data indicated 619 active licensed hunters' harvested 382 elk in 2014, with an overall success rate of 62%. 2014 harvest success decreased 8% from 2013 harvest. 2014 bull harvest (n=138) was a 1% decrease from 2013. Antlerless harvest (n=240) decreased 19% in 2014. This harvest rate appeared high in respect to the population estimate.

Population

In 2014, we selected the TSJ,CA,MSC model again to simulate elk population dynamics in the Shirley Mountain herd unit. This model was the only model in the 2014 suite of models which did not cease functioning due to harvest rates. The 2014 observed bull ratios were replaced in the model with an average because they were not considered representative. The 2014 postseason population estimate was plausible; however, the trajectory in trend for this model's annual population estimates appears unrealistic. The 2014 postseason population of 760 elk is thought to be low, because our classification sample of almost 500 elk was obtained from a ground survey in a relatively small portion of the herd unit. Field managers speculated there were 750 – 1,200 elk in the herd unit.

Preliminary data from the Dunlap Wind Farm elk telemetry project has documented antidotal elk interchange between the Shirley Mountain and Laramie Peak/Muddy Mountain herd units. The proportion of interchange will be reported at the conclusion of this research project. This factor may contribute along with poor classification data to the population model's inability to provide estimates which are comparable to field observations and supported by the annual harvest rates. Ultimately, we will be unable to develop more accurate population estimates for this herd unit without conducting abundance surveys or collecting long-term juvenile and adult survival estimates.

We rated this model as poor, in our evaluation. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model (Morrison 2012).

Management Summary

The 2015 Shirley Mountain Herd Unit hunting seasons were proposed the same as the previous two seasons, and will continue to provide opportunities to reduce the overall elk population and reduce bull ratios towards recreational parameters. Elk numbers appear to be stable to decreasing in trend. The continued operation of the Beer Mug Mountain Hunter Management Area has provided additional harvest opportunities for many elk hunters in this herd unit.

In 2014 we conducted a hunter attitude survey regarding a proposal to implement a Type 9 archery only license in this herd unit. Results of this survey indicated surveyed hunters supported a Type 9 hunting opportunity (APPENDIX I). However, survey response rate was poor (7%), and there was a fair amount of opposition to Type 9 hunts for this area at public meetings. Therefore, we did not propose a Type 9 license in the Shirley Mountain elk herd unit in 2015.

2014 Elk Hunt Area 16 hunter attitude survey regarding Type 9 archery only licenses

Conducted by: Corey Class, Laramie Region Wildlife Management Coordinator

Survey Summary

In late summer of 2014 the Wyoming Game and Fish Department developed and sent out an invitation to participate in a Type 9 (archery only) elk hunter survey online to 326 randomly selected Type 1 and 4 elk hunters from Hunt Area 16. The survey process was initiated due to a high demand for Type 9 hunting opportunities for elk demonstrated during the previous year's season setting process. The pool of hunters included all hunters who applied for Type 1 or Type 4 licenses over the past 3 years. A power analysis was conducted to determine how many surveys would need to be obtained using an assumed response rate of 30%. This assumption proved to be optimistic, with only 28 (7%) people responding to the survey. Overall, respondents appeared to be split somewhat evenly either in favor of, or not in favor of, Type 9 elk licenses in Hunt Area 16.

Survey Question Results

1. What weapon do you prefer to use when hunting in elk Hunt Area 16?

Archery 13
Firearm 15

2. Have you ever archery hunted elk in Hunt Area 16?

Yes 16
No 12

3. For Elk Hunt Area 16, would you support the addition of a Type 9 license (archery only) hunting opportunity?

Neutral	4
Somewhat Support	3
Strongly Support	14
Somewhat Oppose	2
Strongly Oppose	5

4. If you strongly support or somewhat support a Type 9 (archery only) hunting opportunity, what format would you prefer?

- Choose your weapon - Only Type 9 hunters can hunt the archery season, which would mean a "choose your weapon season" while Type 1 hunters would only be able to hunt the rifle season.
- Split - Only Type 9 hunters can hunt the first two weeks of September, but both Type 9 and Type 1 hunters can hunt the last two weeks of September.
- Share - Type 9 hunters and Type 1 hunters hunt archery season together.

Choose your weapon	11
Split	5
Share	1

5. Have you applied for Type 9 (archery only) elk licenses before?

Yes 3 (Hunt Areas 38, 39, or 54)

No 24

6. If you support Type 9 (archery only) hunting opportunities in Elk Hunt Area 16, Why?

It may increase my odds of drawing this hunt 16

It may improve the quality of the hunting experience 12

It will reduce hunter crowding 11

Other (see raw data) 2

7. Would you continue to apply for a Type 1 Elk License in Hunt Area 16 if the special archery season was removed and became a Type 9 only season?

Yes 26

No 25

FIGURES

Comments: For 2014, the TSJ,CA,MSC model was selected due to the most plausible population estimate. However, this model's steep decreasing trajectory is suspect. The data set for this herd has accuracy issues related to survey sample sizes for classification data. Interchange of elk with surrounding herd units has been documented, leading to the question of whether this is a closed population.

Management Evaluation

Current Management Objective: 1) Landowner and hunter satisfaction; Target goal: \geq 60% 2) Male “quality”; Target goal: \geq 61% branch antlered bulls in harvest survey

2014 Post-season Objective Results: 1) 39% landowners either satisfied or very satisfied, 2) 61% sportsmen were either satisfied or very satisfied, 3) 95% branch antlered bulls

2015 Post-season Results: NA

Management Strategy: Special

2014 Sportsmen Satisfaction Survey Results: 61% Satisfied, 27% Neutral, 12% Dissatisfied

Management Issues

The management objective for this herd was changed in 2012 from a post-season population objective of 40 elk to a nonnumeric population objective based on landowner and hunter satisfaction and the percentage of branch antlered bulls in the harvest. The management strategy was changed from recreational to special. We will follow trends over time to make management decisions based on constituent satisfaction and bull harvest parameters. There is not a working model for this herd unit due to our inability to collect adequate population data.

This herd unit has been difficult to manage based on our inability to collect adequate herd composition data along with field harvest data. Based on field personnel and landowner

observations we estimate there are over 400 elk in the Rawhide Elk Herd, with the population expanding south of the North Platte River into Goshen, Platte and Laramie Counties. There have been several public meetings to address the increasing population, and as a result the herd boundary was expanded south to the Colorado border for the 2012 season. Additionally the portion of Area 3 north of U.S. Highway 26 was changed to a general season for the 2014 season (the southern portion was changed to a general in 2011).

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the Rawhide Elk Herd Unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on elk. Mild fall temperatures and lack of persistent snows allowed for elk to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Rawhide Elk Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

There are no established habitat transects for this herd unit. Recent fire activity in 2012 and 2010 burned over 20,000 acres will likely improve elk habitat by reducing competition from encroaching conifers on perennial grasses and forbs, which provide key elk forage.

Field/Harvest Data

Harvest success and effort has fluctuated the past five years, and when the 2014 harvest data is compared to the five-year average success and effort decreased. Harvest is driven by access and if hunters are limited to public land, success decreases and effort increases. Finding elk in this herd unit can be difficult due to landownership patterns. Access is restricted to the Broom Creek HMA north of US Hwy 26 and is dependent on crop damage south of US Hwy 26. A majority of landowners do not want elk south of the highway and are willing to allow access. In 2011 elk were plentiful and hunters were successful. In 2012 the severe drought displaced elk and they were not found in traditional places (i.e. alfalfa fields). In 2014 above average spring and summer precipitation re-distributed elk which increased forage production and as a result elk were not dependent upon irrigated crops. The high percentage of branch antlered elk is indicative of the quality of bulls and the amount of private land that provides sanctuaries to allow bulls to reach maturity.

Licenses numbers have fluctuated from 50 to 200 over the years. Starting in 2011 that portion of Hunt Area 3 south of U.S. Highway 26 became a general season. After several public meetings over the past three years coupled with a landowner survey it was decided to convert that portion of Area 3 north of US Hwy 26 from a limited quota area to a general hunt area. This will simplify the management by allowing hunters with a general license the opportunity to hunt in other general areas in the state if they are not successful in hunt area 3. Population and damage issues will be easier to address with this type of season structure as well.

Since this herd unit changed to a satisfaction management evaluation and the percent of branch antlered bulls in the harvest we no longer collect classification data.

Landowner/Hunter Satisfaction Survey Results

The hunter satisfaction survey is not available at the time that this report was due. The landowner satisfaction survey showed that 39% of the landowners were satisfied, 26% were neutral and 26% were dissatisfied. Sportsmen were 61% satisfied with their hunt. There were 23 surveys returned for a 30% return rate, slightly lower than 2013, which had a return rate of 41%. Based on the past two years of landowner satisfaction surveys it appears we need to make an effort to improve landowner satisfaction. The hunt area is split on how landowners want to manage elk. Based on input from the field, meeting and survey comments, about half of the landowners want to reduce elk and the other half want to manage for trophy bulls. Bringing their satisfaction up to 60% will be a challenge. The high percentage of satisfied sportsmen is somewhat surprising given the number of complaints received from the field that hunters could not find trophy class bulls or cow elk later in the season. However, there were several trophy class bulls taken during the archery and early rifle season just north of Guernsey on or adjacent to the Guard Camp. The percent of branched antlered bulls in the harvest survey was 95%. Our ability to manage this segment of the population is limited due to access and adult bulls within the harvest will likely remain high.

Management Summary

In summary the 2015 season is designed to reduce elk numbers throughout the entire hunt area by having both portions (north and south of US Hwy 26) a general firearm season from Sept 15-Oct 14, and then 109 days of a general license any season elk south of US Hwy 26 and a 168 day season for the Type 6 licenses. We hope to attain a harvest of 140 elk.

Management Evaluation

Current Management Objective: 100 (80 – 120)

Management Strategy: Special

2014 Postseason Population Estimate: 266

2015 Proposed Postseason Population Estimate: NA

Moose in the Snowy Range herd unit are managed toward a numeric objective of 100. A moose population model has not been developed for this herd unit. The herd is managed under a special management strategy. The objective was last reviewed in 1997.

Herd Unit Issues

The Snowy Range herd unit stretches across southern Wyoming, along the Colorado border, from Baggs to Cheyenne. Moose are found year-round in areas on Pole Mountain, Sierra Madre Mountains, and most notably, the Snowy Range Mountains. These moose descended from moose transplanted in Colorado and were not native to this area historically. Challenges for managing moose in this herd unit include a rapidly changing forest ecosystem, high infestation rates for parasites, and human conflict/safety. Limited population monitoring for moose has been an issue in this herd unit.

Weather

Weather in this herd unit was relatively normal during the past bio-year. This weather pattern most likely had a neutral to positive influence on moose. For specific meteorological information for the Snowy Range herd unit the reviewer is referred to the following links:

<http://www.ncdc.noaa.gov/temp-and-precip/time-series/>

Habitat

Moose habitat conditions are currently being monitored across Wyoming and in the North Park, Colorado area through a University of Wyoming project. Preliminary results published in a recent annual report for this project indicated the Snowy Range's willow habitat quality and moose fitness were relatively low when compared to the other areas (Jesmer, et. al. 2014).

Habitat conditions improved in 2014 with an increase in timely seasonal precipitation. However, much of the transition and winter ranges were severely impacted by the drought conditions experienced in bio-year 2012. No WGFD moose habitat production/utilization data was available for this herd unit. However, annual production rates were assumed to have improved from the previous year, while utilization rates on winter ranges were assumed to have continued to be high.

Field Data

Traditionally there has been little allocation of funding in this herd unit to collect moose classification data. Moose classification data has been collected incidentally during annual mule deer and elk classification surveys. In 2014, no additional hours of helicopter flight time was allocated to collect moose classification data in the Snowy Range herd unit. A classification sample of 52 moose was collected in December of 2014 in conjunction with mule deer and elk surveys. Eleven (11) of the 52 moose observed during the 2014 survey were in Hunt Area 41, on the Sierra Madre range. The 2014 classification ratios were 100 bulls/100 cows and 36 calves/100 cows.

Harvest Data

In 2014, the weighted harvest estimates indicated 48 hunters harvested 23 bulls, 22 cows and 2 calves (lab data indicated 1 calf). A total of 2 illegally harvested moose were documented in 2014. Male lab-aged tooth samples (n=37) indicated this year's median age and percentage of the bull harvest ≥ 5 years of age, were within the "prime-age bull" class (Figures 1, 2 and 3) (Thomas 2008). Age class distribution from female lab-aged tooth samples (n=17) indicated 47% of the antlerless moose harvest were ≤ 2 years old (Figure 4).

Median age for tooth samples from harvested bulls increased in 2014 and this increase was attributed to a reduction of 5 licenses being allocated for the 2014. The 2014 median bull age increased to 5 years of age which was an improvement of 1 year in age from the 2013 season, and within the parameters for the "prime-age bull" class. The Snowy Range has a reputation for producing trophy quality bulls. An objective for managers is to sustain both quantity and quality for the bull segment of this moose population.

The reported ages for harvested antlerless moose in 2014 was similar to the 2013 results even though license numbers had been reduced by 10 licenses. Although the proportion

of antlerless harvest ≤ 2 years in age (47%) was acceptable, it was assumed this proportion would increase in 2014 with the decrease in license numbers. As stated earlier in this report, making inferences from small or incomplete data sets has hampered the ability of managers to make management decisions of significant consequence for this herd unit.

Figure 1. Median age of bulls harvested for the Snowy Range Moose herd unit, from lab aged teeth (n=20), Wyoming, 2014.

Figure 2. Average (3-year running) median age of bulls harvested for the Snowy Range Moose Herd Unit, from lab aged teeth (n=20), Wyoming, 2014.

Figure 3. Annual Percentages of the bull harvest ≥ 5 -years in age from Snowy Range Moose Herd Unit, from lab aged teeth (n=20), Wyoming, 2014.

Population

A Wyoming Spreadsheet model has not been developed for this herd unit. A moose abundance survey was completed in the Snowy Range herd unit in March 2015 (Appendix I). A total abundance estimate of 266 ± 56 (90% CI) ($SE = 34$) moose was produced for this herd unit. The results of the sightability survey provided managers with a plausible abundance estimate for moose wintering in the Snowy Range herd unit. The abundance estimate will be useful in constructing a population model and making future harvest recommendations for moose in this herd unit.

Management Summary

In 2015, license numbers and hunting season lengths remained the same as they were in 2014. We decreased license numbers for the 2014 hunting season due to concerns for our ability to maintain trophy quality in the bull harvest. This decrease was also done in part as an effort to become more conservative with harvest rates; as a precaution in case moose numbers were approaching our postseason management objective of 100 moose.

Current Herd Specific Studies

A new collaborative study initiated in fall 2014 by the Wyoming Cooperative Fish and Wildlife Research Unit and the Wyoming Game and Fish Department presents an excellent opportunity to examine the relationship between moose habitat use and seral changes brought about by bark beetles. By making use of an existing GPS dataset collected prior to extensive beetle damage (Baigas 2008), comparing it to new GPS data, and examining current individual movement strategies through the lens of body condition, this project will provide new information on the status of moose in the Snowy Range and their response to its beetle-killed forests.

The project began its field component in March 2015. Thirty (30) female moose (29 adults and one yearling) were captured via helicopter darting on winter habitats within and surrounding the Medicine Bow National Forest. Moose were fitted with GPS store-on-board collars set to collect 90-minute fixes. The fix-rate is identical to that used in the previous study, which will allow us to compare movement strategies and space use of moose prior to and following the extensive bark beetle damage. Collars will remain deployed for a period of two years, during which study animals will be recaptured twice per year to gather longitudinal data on demography and body condition (measured via ultrasonography). Monitoring body condition in the context of pregnancy (during winter) and lactation costs (in summer) will allow the project to critically examine the habitat quality of the Snowy Range, with the goal of understanding where the herd sits relative to nutritional carrying capacity.

ESTIMATING MOOSE ABUNDANCE FOR THE SNOWY RANGE HERD UNIT IN WYOMING

May 2015

Will Schultz and Corey Class

INTRODUCTION

Moose (*Alces americanus shirasi*) were introduced in north central Colorado during the 1970s and 1980s and subsequently migrated north into portions of adjacent Wyoming mountain ranges. The first documented sighting of a moose in the Snowy Range herd unit occurred in 1981. Since 1981, moose have continued to expand in range and numbers throughout the Snowy, Sierra Madre and Laramie Mountain ranges of south central Wyoming.

Wyoming Game and Fish Department (WGFD) established a postseason management objective of 100 moose for the Snowy Range herd unit in 1987. By 2000, WGFD assumed the moose population had increased beyond the management objective and established the first hunting season for moose in this herd unit. Annual moose hunting seasons have been offered continuously in this herd unit since 2002. Harvest recommendations for a big game population such as the Snowy Range moose are difficult to formulate without the appropriate population data. Uninformed recommendations may result in over harvest or extirpation if too many moose are harvested annually, or it may result in reduced sustainability for moose browse if too few moose are harvested annually.

Past moose population monitoring in the Snowy Range herd unit consisted of collecting moose sex and age composition data incidentally while completing elk and mule deer postseason composition surveys. WGFD had not developed an abundance estimate for moose in the Snowy Range herd unit, either from abundance surveys or from a population model. In recent years, this herd unit has become the premier moose hunting and viewing destination in Wyoming. Insuring moose in this herd unit are managed sustainably has become a priority for WGFD. These factors cumulatively resulted in WGFD conducting an abundance survey in March 2015 to determine the current population status for moose in the Snowy Range herd unit.

SURVEY AREA

The Snowy Range herd unit is comprised of moose Hunt Areas 38 and 41 in southern Wyoming (Figure 1).

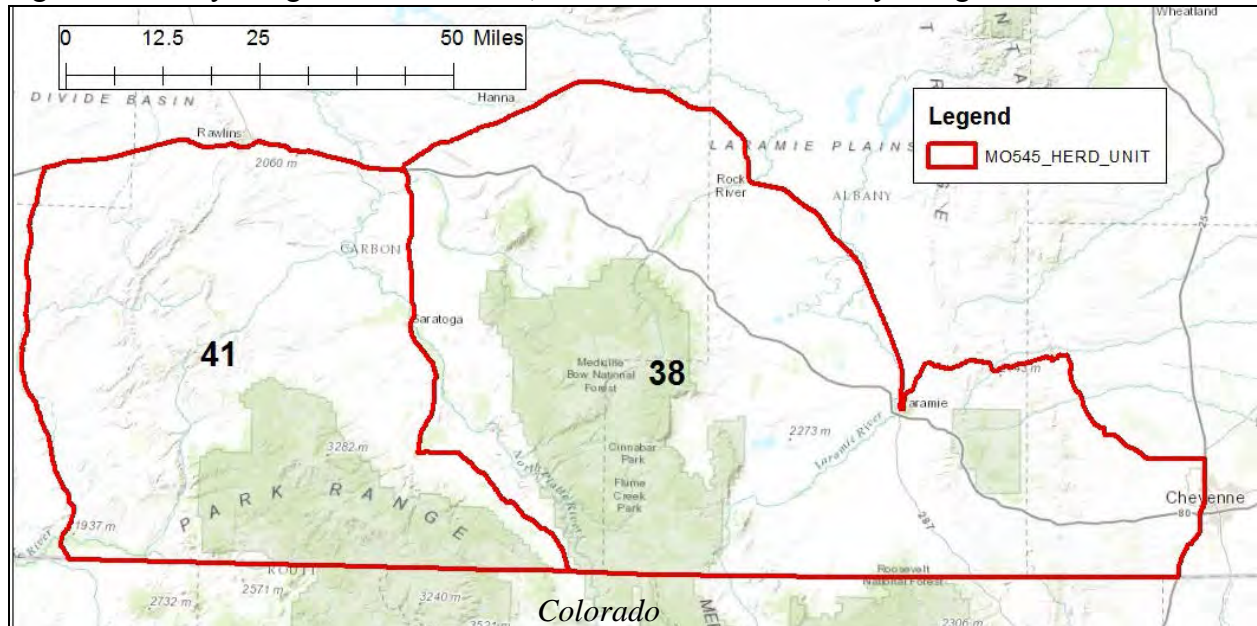

METHODS

Survey Area Selection

Moose abundance surveys had not been previously conducted in this herd unit and therefore some extrapolation of where moose might potentially be located in late winter was required.

WGFD managers associated with this herd unit mapped out locations known to be occupied by moose during winter using data from the WGFD Wildlife Observation System. Additionally, resource selection model results from Baigas (2008) were used to identify areas assumed to

Figure 1. Snowy Range moose herd unit, Hunt Areas 38 and 41, Wyoming.

contain suitable winter moose habitat. Data from these two sources were incorporated to delineate an area assumed to be potentially occupied by moose in late winter.

A stratified random sample survey of the potentially occupied area was selected due to time and budgetary restraints. The potentially occupied area was divided geographically into survey search units (subunits) ($n = 42$) using features distinguishable from the air such as roads and waterways. Subunits were stratified by WGFD managers as either low or high strata with respect to assumed relative moose numbers (Figure 2). A random sample ($n = 9$) of the 31 low strata subunits were selected to be included in the survey. All ($n = 11$) high strata subunits were also included the survey.

Figure 2. Subunits for areas potentially occupied by moose in the Snowy Range herd unit, Wyoming.

Survey

A sightability survey technique (Anderson 1994, Anderson and Lindzey 1996) was selected to determine moose abundance in the Snowy Range herd unit. The survey was conducted using a Bell® Jet Ranger helicopter (Bell Helicopter Textron Inc, Fort Worth, Texas, USA) supplied by Northern Skies Aviation (Laurel, Montana, USA). The survey was conducted 14 March - 22 March 2015. Helicopter speed was maintained at 40-50 knots, at an altitude of 100-200 ft. above ground during survey flights. Survey flight lines were flown in a manner to provide for the possibility to detect all moose groups in between the survey lines. All habitat in the subunits assumed to be occupied by moose was surveyed. Areas occupied by humans and confined livestock (e.g. houses and ranch yards) were excluded because of safety considerations. Seventy-three (73) hours of flight time were used to complete the survey.

Two (2) observers occupied the helicopter on all survey flights. Observers were Bill Brinegar, Biff Burton, Corey Class, Rick King, Lee Knox, and Will Schultz. The primary observer was seated in the left front seat of the helicopter and was responsible for observing the ground in front of and to the left of the helicopter. The secondary observer was seated in the right rear passenger seat and was responsible for observing the ground to the right the helicopter. The secondary observers also recorded observation data on paper survey forms and collected waypoints and flight tracks using a Garmin® (Garmin International Inc., Olathe, Kansas, USA) handheld GPS unit. Sightability variables recorded for each moose group observed included: waypoint number, moose group size, activity of the most active moose in the group, percent of snow cover, vegetation class, and percent of vegetative screening cover. Observations of other wildlife were also recorded incidentally.

RESULTS

A total 134 moose were observed in 86 groups (Attachment A). Moose group observation and sightability variable data were analyzed using the Wyoming Hiller-Soloy moose model in the Aerial Survey computer program (Unsworth, et. al. 1999). A total abundance estimate of 266 ± 56 (90% *CI*) ($SE = 34$) moose was produced for this herd unit (Attachment B). Sex and age ratios from the survey yielded 38 calves, 16 yearling bulls, and 53 adult bulls /100 cows.

DISCUSSION

The abundance estimate of 266 ± 56 moose was considered a minimum estimate based on an antidotal comparison between unmarked moose and marked (radio-collared) moose observed during the survey. During the 7 days prior to the sightability survey, 30 moose in this herd unit were chemically immobilized using a dart gun fired from a helicopter, handled for sampling, and fitted with radio-collars. Twenty-seven (27) of the 30 radio-collared moose were located within subunits which were surveyed during the time of the survey. Four (4) of the 27 radio-collared moose in the surveyed subunits were observed during the survey. Several of the radio-collared moose not observed during the survey were relocated using radio telemetry immediately after the respective subunit survey was completed. These relocated radio-collared moose appeared to be actively evading the helicopter by moving into dense cover types. The inability of observers to locate the radio-collared moose during the initial survey flight indicated sightability correction rates from the Wyoming Hiller-Soloy moose model may under estimate abundance for moose group observations in dense cover.

Sex and age ratios from the sightability survey were similar to the results of the postseason classification survey completed in December of 2014 (Table 1) with the exception of the adult bull ratio. Adult bull ratios from the sightability survey were lower than the ratio from the postseason classification survey. The lower adult bull ratios from the sightability survey may have been due to bulls which had lost their antlers being classified as unknowns during the sightability survey.

Table 1. Moose sex and age ratios from a postseason classification survey completed December 2014, and a sightability survey completed March 2015, in the Snowy Range herd unit, Wyoming.

Survey	Sample	Unknown	Ad. Bulls	Yr. Bulls	Calves	Cows	Ad. Bulls /100 Cows	Yr. Bulls /100 Cows	Calves /100 Cows
Class.	52	0	20	2	8	22	91	9	36
Sight.	134	18	29	8	23	56	53	16	38

The results of the sightability survey provided managers with a plausible abundance estimate for moose wintering in the Snowy Range herd unit. The abundance estimate will be useful in constructing a population model and making future harvest recommendations for moose in this herd unit.

Management Evaluation

Current Management Objective: 20,000 (16,000-24,000)

2014 Post-season Population Estimate: ~12,000

2015 Post-season Population Estimate: ~12,200

2014 Hunter Satisfaction Survey Results: 64% Satisfied

Management Strategy: Recreational

2014 Sportsmen Satisfaction Survey Results: 64% Satisfied, 20% Neutral, 15% Dissatisfied

Herd Unit Issues

The management objective for the Goshen Rim Mule Deer Herd Unit was changed from 25,000 to 20,000 and Hunt Areas 15,16,55,57 were combined into Hunt Area 15 as a result of internal recommendations and public input during the 2013 herd objective review process. The management strategy is recreational management with a post-season buck ratio range of 20-29 bucks:100 does.

The 2014 post-season population estimate was about 12,000 with a stable population. Restricted access makes it difficult to manage this herd. Access is driven by isolated private land experiencing damage and small parcels of state, BLM lands, and private lands enrolled into the Department's PLPW program.

Without paying a trespass/trophy fee or hiring an outfitter, hunters have a difficult time harvesting a mature mule deer buck. Landowners and hunters would like to see an increase in mule deer, but without major habitat revitalization (for part of the year mule deer are dependent on irrigated and dryland agriculture fields) this herd unit will most likely remain around 12,000 mule deer. Buck ratios are anticipated to remain on the higher end of the recreational management strategy due to private land (92% of the occupied habitat). Public land hunters will continue to have a difficult time finding a mature buck due to the majority of land being held in private ownership.

Major landscape changes have been occurring in the southern portion of the herd unit. Urban sprawl continues to increase north and east of Cheyenne as well as industrial (methane production) development in Laramie County. The USDA's Conservation Reserve Program (CRP) has experienced a decline in productivity and quality of perennial forage throughout the herd unit. The conversion of dryland (wheat fields) cropland to CRP in the past provided favorable fawning and winter cover for mule deer. These stands are now monotypic stands of unfavorable perennial grass (i.e. smooth brome and crested wheatgrass) and no legume component, providing little if any habitat benefits.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the Goshen Rim Mule Deer Herd Unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on mule deer. Mild fall temperatures and lack of persistent snows allowed for mule deer to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Goshen Rim Mule Deer Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in Spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of

“representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In Spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

This herd experienced a sharp decline in 2012 following the worst drought recorded since the 1930's, and since then has been fluctuating around 12,000 mule deer. General licenses have focused harvest on the male segment of the population with little effort to remove females. There were 350 Type 6 licenses available for the 2014 season for some doe harvest opportunity and address damage situations. On average less than 1 percent of the female population is harvested. Chronic wasting disease is not as prevalent in this herd when compared to the Laramie Mountains and South Converse Mule Deer Herd Units, but the long-term prevalence rate average of 11% is most likely impacting population performance to an unknown extent.

In 2014 fawn ratios exceeded 66 fawns: 100 does (81 fawns:100 does) for the first time in over ten years, which is needed to increase a population (Unsworth et al. 1999). Despite buck ratios well within the recreational management range, (28 bucks:100 does in 2014) it appears based on personnel and hunter observation the buck ratios on accessible lands are likely on the lower end of the management strategy.

In 2014, 30% of the field harvest data was comprised of yearling bucks, which is the highest sample size in five years. The majority of yearling mule deer that are aged in the field typically come from public land where hunters are usually less selective, so the 30% is not surprising. Yearling harvest data correlated well with post-season yearling classification data, fawn ratios increased by 100% from 2013 to 2014. On public land the majority of mature male deer are typically 2-3+ years old. On private land where access is controlled, the average age is 4-6+ years old. Based on field observations public land hunters typically harvest younger deer, lending credibility to a lower buck: doe ratio on the limited amount of public lands.

Since 2012 antler class data has been collected from harvested mule deer, then in 2013 from classified mule deer to gauge buck quality. Antler class data is broken down into three classes: 1) Class I- ≤ 19 ", 2) Class II- 20-25", Class III- ≥ 26 ". Typically harvest class data is similar to classification class data (see tables from JCR). The only significant observation when comparing antler harvest data and classification antler data is the percent of Class II deer increased in 2014 compared to 2012/13, and 2014 was a mirror image of the classification antler class data. Based on these observations it appears the harvested deer are representative of male age cohorts within the population, which indicates the season structure is working to maintain the recreational management guidelines. The hunter satisfaction survey showed that 64% of the hunters were satisfied or very satisfied, similar to 2013. This level of satisfaction is somewhat

surprising given the negative comments received from hunters by field personnel. Hunters continue to comment on lack of mature bucks and overall lack of deer.

Harvest Data

Hunter success (49%) was slightly higher than the five-year average of 47%, and hunter effort (8.3 days/harvest) was similar to the five-year average of 8.0 days per harvest. Access continues to be an issue in this herd unit with 92% of the occupied habitat consisting of private land. The only major access is the PLPW's Hunter Management Program on the Guernsey Guard Camp, walk-in areas, and the various Wildlife Habitat Management Areas. Access for the most part is driven by damage, which is the reason for the few Type 6 licenses. Access for buck harvest is extremely difficult unless a hunter is willing to pay a trespass fee or hire an outfitter. Private land ratios inflate overall buck ratios to the higher end of the recreational management strategy.

Population

The "Time-Specific Juvenile and Constant Adult Survival" (TSJ,CA) spreadsheet model was chosen to use for the post-season population estimate of this herd. The model has a slightly higher AIC value but did have the best fit compared to the other two models. Given the better fit of data and perceived population trend by personnel, landowners and hunters, this seemed like the most plausible model. Juvenile survival ranges varied from a high of 90% to a low of 40% with an average of 60%. The 2007 winter was mild, so a high survival rate is plausible. Hunters and landowners would like to see a continued increase in the population, however, given poor fawn production CWD, and poor shrub conditions an increase is not likely in the near future. This models ranks fair. The only data available is classification and harvest data.

Management Summary

Hunting seasons in this herd unit have traditionally started on October 1 and run for 11 to 14 days for the general season with limited doe/fawn harvest opportunity running later. The 2015 season structure will remain the same as the 2014 season; general season October 1-14 and 350 Type 6 licenses. Department personnel will work with landowners and hunters to distribute harvest as damage issues arise. The Region T licenses will remain at 400. In 2014, 93% of the licenses were active, similar to the number of hunters that went to the field in 2013 when 500 Region T licenses were available. Based on harvest data, harvest increased, success increased, and effort decreased compared to 2013. The current number of Region T licenses seems adequate.

If we attain the projected harvest of 790 deer and observe normal fawn production the mule deer population of 12,200 will continue to remain well below the objective of 20,000.

Management Evaluation

Current Post-season Population Objective: 25,000 (20,000-30,000)

2014 Post-season Population Estimate: ~17,300

2015 Post-season Population Estimate: ~15,500

Management Strategy: Recreational

2014 Sportsmen Satisfaction Survey Results: 59% Satisfied, 20% Neutral, 21% Dissatisfied

Herd Unit Issues

The management objective for the Laramie Mountains Mule Deer Herd Unit was reviewed in 2014 and as a result of internal and public involvement the objective was decreased to 20,000 mule deer, and Hunt Areas 59, 62, 63 were combined into Hunt Area 59, and Hunt Areas 64, 73 were combined into Hunt Area 64. The recreational management strategy will remain in place with a post-season buck ratio range of 20-29 bucks:100 does.

The 2014 post-season population estimate was about 17,300 with the population fluctuating around 17,500. Chronic wasting disease (CWD) has been detected in this herd for well over two decades. The average prevalence rate since 1997 is 22%, contributing towards the suppression of this herd. Management strategy has been very conservative with little doe harvest to try and increase the herd. Approximately 50% of the herd unit is private lands which affects our ability to provide opportunity.

The Arapahoe wild fire in 2012 will have habitat effects for years to come. In some areas perennial vegetation is responding. In other places the ground appears sterile with little to no vegetation growth. Mule deer have been harvested in the burned area in 2012 and 2013. Mule deer occupation in burned areas was also documented during the winter of 2013. In the long run this major fire will be positive for ungulate habitat. It will take time to see the major re-vegetation events and herd population response.

Landowners and sportsmen would like to see more mule deer. To address this desire the Type 6 license are proposed to stay at a conservative number.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the Laramie Mountains Herd Unit. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on mule deer. Mild fall temperatures and lack of persistent snows allowed for mule deer to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Laramie Mountains Mule Deer Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game species. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunkbrush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of “representative habitats” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

In spring 2015, population biologists and habitat managers will be working together to modify habitat monitoring techniques utilized statewide and to improve overall consistency among the regions. Identification of key herd units per big game species, identification of representative monitoring locations in all seasonal ranges per big game species (summer, transition, winter), and development of correlations to amounts of and timing of precipitation will help improve data collected and result in our abilities to more strongly correlate management decisions for populations based off habitat conditions.

Field Data

Fawn ratios of 81 fawns:100 does in 2014 were the highest observed in over ten years, allowing for population growth. According to Unsworth et al. (1999) populations increase when fawn ratios are above 66 fawn: 100 does. Buck ratios of 39 bucks:100 does were well above the recreational management strategy. However, finding a mature buck on public land is often difficult. Yearling bucks classified in 2014 (11 yearling bucks: 100 does) were similar to the five-year average of 10 yearling bucks:100 does. The 2014 sample size was the highest collected in the past ten years (n=3,012), lending credibility to herd composition data.

Field harvest data in 2014 was somewhat similar to post-season classification data. Seventeen percent of the field harvest data was comprised of yearling bucks, and post-season classification data resulted in 11 yearling bucks: 100 does. A poor fawn crop in 2013 coupled with an increase in harvest pressure on the yearling bucks could explain the slight discrepancy.

Since 2012 antler class data has been collected from harvested mule deer and then starting in 2013 from classified mule deer to gauge buck quality. Antler class data is broken down into three classes: 1) Class I- $\leq 19''$, 2) Class II- 20-25'', Class III- $\geq 26''$.

The majority of mule deer bucks harvested in 2012 were in the Class I category (75%). Then it was split between class II (14%) and Class III (12%) bucks. In 2013 the harvest data is similar to the classification data. In 2014 Class I harvest data and Class I classification data were similar but Class II classification data was 24% lower than Class II harvest data, and Class III classification data was 12% higher than Class III harvest data. Male cohorts follow typical pattern in harvest and herd composition data over their lifespan; typically there is a greater percentage of bucks in the lower antler classes. As deer mature there are fewer left in the population. By comparing these two data sets this more or less holds true. One would expect to see a higher percentage of Class III bucks in classification data since they are observed during the rut with a greater sample size, this also holds true.

Deer were in good condition going into the winter given the excellent habitat conditions in 2014. The average body score taken from 35 mule deer was 17 out of 20. The satisfaction survey showed that 59% of the hunters were satisfied, which was somewhat surprising based on negative comments received from the field that hunters were having difficulty finding mature buck.

Harvest Data

Hunter success in 2014 (52%) was similar to the five-year average of 54% and hunter effort of 10 days per harvest which was significantly higher than the five-year average of 8.4 days per harvest. These data support a stable to decreasing trend in population, which also supports personnel, landowner, and sportsmen observations. The boost in fawn production should help to offset the higher rate of adult mortality due to CWD.

Population

The “Time-Specific Juvenile and Constant Adult Survival” (TSJ,CA) spreadsheet model was chosen to use for the post-season population estimate of this herd. The AIC value was slightly higher but did have a better fit than the other two models. This model was chosen for the following reasons: 1) The model tracks juvenile variability in survival, which is more consistent with this herd unit based on the fluctuations in juvenile composition data, 2) There is a large number of years with classification and harvest data, indicative of the TSJ, CA model, 3) simulated population trends mimic perceived trends observed by local personnel, landowners and hunters. Adult survival was changed in years 2010-2013. Adult survival data from the South Converse Mule Deer Herd Unit CWD study was incorporated from those years since both herd units have high prevalence rates and the Laramie Mountains Herd Unit is adjacent to South Converse. This model is rated as fair. There is not an annual population estimate with a standard error available to anchor the model and results are biologically defensible, giving the model a fair fit. Adult survival was adjusted to .7-.8 instead of the recommended range of .7-.95 to account for chronic wasting disease prevalence rates in years that did not have adult survival data. Hunters and landowners would like to see an increase in mule deer, but given poor recruitment, CWD, and poor habitat conditions an increase in the population does not seem likely in the near future.

Management Summary

Hunting seasons in this herd unit have started on the 15th of October and run between 10-15 days. Late doe/fawn seasons have been used to address damage situations in lower elevations on private land, but the public has overwhelmingly indicated they would like to see more mule deer. The season structure for the general season and Type 6 licenses will remain the same as 2014. Area 60 remains a sought after license for hunters since it provides a chance to hunt into November when bucks are more susceptible to harvest. In order to try and provide more opportunity for the coveted license the number of Hunt Area 60 Type 2 licenses will increase from 150 to 200. Region J licenses will remain the same at 900 to address low deer densities, especially on public lands. Nonresident licenses continue to decrease over the past few years. The 900 Region J quota will be consistent with recent license sales (2012=949, 2013=779 and 2014= 822) and hopefully improve harvest statistics and reduce hunting pressure.

To simplify management and regulations Hunt Areas 59, 62 and 63 were combined into Hunt Area 59 and Areas 64 and 73 were combined into Hunt Area 64.

If we attain the projected harvest of 970 mule deer (890 bucks, 80 does), maintain average fawn recruitment, and take into account CWD prevalence rates the mule deer population will slightly decline and still remain well below the management objective. We predict a 2014 post-season population of about 15,500.

Management Evaluation

Current Postseason Population Management Objective: 15,000 (12,000-18,000)

Management Strategy: Recreational

2014 Postseason population Estimate: ~ 5,600

2015 Proposed Postseason Population Estimate: ~ 5,900

2014 Hunter Satisfaction: 49% Satisfied, 24% Neutral, 27% Dissatisfied

The management objective for the Sheep Mountain Mule Deer Herd Unit is a post-season population objective of 15,000 mule deer. The management strategy is recreational management with guidelines to maintain a post hunt buck ratio of 20 to 29:100 does. The objective and management strategy was reviewed in the spring of 2015 (appendix B).

Herd Unit Issues

The Sheep Mountain herd unit encompasses hunt areas 61, 74, 75, 76 and 77. Landownership varies from mostly private lands with limited public access, to large portions of public lands. The 2014 post-season population estimate is approximately 5,600 with the population stabilizing after a decline from 7,500 in 2009. The Sheep Mountain Herd Unit historically has one of the lowest hunter success rates in the state, even when we estimated a higher population. Most of the herd's summer range is in dense lodge pole or spruce forests that were once heavily logged in the 1960s and 1970s. There is a large scale forest die off from pine and spruce beetles, and though we think it will be beneficial, the effects are unknown. Winter and transition range is limited. In 2012 there was a large scale wildfire that is thought to be beneficial in the long run, but currently has caused displacement. Black bear and lion mortality limits were liberalized, and season lengths were increased. There is an ongoing predator removal project with the Albany County Predator Board focusing on key mule deer parturition areas in the Sheep Mountain herd unit to evaluate the effect of coyotes on fawn recruitment (Appendix A). We are currently in the middle of a mule deer initiative process with this herd unit. So far it has helped spark more discussions with the WGFD, federal agencies, and non-government organizations that should turn into some good on the ground improvements that will be beneficial.

Weather

Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. The fall of 2013 in the Laramie Valley received the highest amount of precipitation on record. 2014 in the Laramie Valley experienced a mild winter, above average precipitation in the spring, followed by an average summer, and ending once again with above average precipitation in the fall. Mild fall temperatures and lack of persistent snows allowed for big game species to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to year 2012. Utilization rates of key winter range shrubs documented in spring 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The Squirrel Creek Fire (Figure 1.) started on June 30th 2012, burning about 11,000 acres of transitional and crucial mule deer winter range within the Sheep Mountain Herd Unit. Habitat conditions were old and decadent and we expect this fire to greatly benefit range conditions in the future. During the summer of 2014 field personal observed a high success of re-sprouting from true mountain mahogany and antelope bitterbrush. However, on steep south facing slopes

and areas that burned at higher temperatures there is substantial cheatgrass encroachment. The USFS has not finished the EIS to allow aerial application of herbicide, and until this is complete there is little that can be done.

Figure 1. Squirrel Creek Fire Perimeter with Sheep Mountain Mule Deer crucial winter range.

Field Data

In 2014, 580 deer were aerially classified within the herd unit. This effort did not meet the classification objective of 1,110 due to a mild fall with little snow and warmer than average temperatures, causing deer to be less concentrated on the winter ranges. Fawn ratios increased from 55:100 does in 2013 to 75:100 does in 2014. Mule deer herds state wide saw similar increases in fawn ratios and it is mostly attributed to the excellent fall and spring moisture in 2013 and 2014. Youth and archery hunters harvested 36 does and fawns in 2014, less than 1% of the total female population. 2014 was the second year an antler point restriction was implemented. The buck ratio remained at 26:100 does from 2013 to 2014, reaching the high side of recreational management, but 40% of the bucks classified were yearlings. We are also certain that we missed mature bucks during our classification flight due to the mild weather conditions and the buck ratio mostly like does not truly reflect what is on the ground. We implemented a new ranking system in our classification in 2013 that places bucks into 3 classes based on antler spread: class I is 19 inches or less, class II is 20-25 inches, and class III is 26 inches or greater. Of the total number of bucks classified, class I made up 71%, class II was 18%, and class III was 11%, which is comparable to 2013. Total active licenses remained comparable to 2013 at 1,100, but over the last decade we have lost 1,000 resident hunters. Nonresident hunters decreased by 130, which was expected with the reduction in region D quota. Hunter effort decreased by 10 days to 24, and hunter success increased by 10% to 24%, indicating hunters are finding more mature bucks. However 24% hunter success is still far below the state wide average of 66%, and is one of the lowest herd unit success rates in the state. The hunter satisfaction survey indicated that 50% of hunters were satisfied or very satisfied with their hunt, up from 40% in 2013, with 23% remaining neutral in the survey.

Harvest Data

2014 was the third year of a weeklong season, and the second year of an antler point restriction. Harvest has been on a steady decline from a high of 980 deer in 2004 to 190 deer in 2013. The 2014 harvest saw a slight increase to 290 deer. Of the estimated 290 mule deer harvested, 36 were does and fawns, and 29 of those were harvested with archery equipment. Even though the female harvest makes up 10% of the total harvest, it is less than 1% of the total female population and is not substantial enough to affect the population, but it is perceived poorly by the public. The 2014 season structure was mostly well received; hunters and landowners perceived it as the Department is addressing their concerns with this herd unit. Overall public comments are that the herd is increasing.

Population

Time-Specific Juvenile & Constant Adult Survival (TSJ, CA) spreadsheet model was chosen for this Herd Unit. This model has the lowest AIC score of 167 and a Fit of 71, and estimates the population declining from a high of 7,500 in 2009 to the current estimate of 5,600. This model is ranked as fair; there is 15-20 years of data; ratio data available for all years in model; juvenile and adult survival estimate with standard errors obtained from adjacent or other similar herds; model aligns fairly well. We were able to get several years of fawn and adult survival rates from radio collared studies in Colorado that took place near the Wyoming border. With this information the model provides a more believable estimate considering the classification samples and fawn ratios. Field staff, landowners, and hunters all agree the population is down and the herd should be managed conservatively.

Management summary

If we attain the projected harvest of 335 deer, and have a fawn ratio of 66:100 does or higher, the herd should start to rebound. Using 66:100 (Unsworth 1999) does as our predicted fawn ratio, we estimate a 2015 post-season population of about 5,900. The 2015 season will be 7 days with a 3 point or better antler restriction to maintain higher buck ratios, and address public concerns. We feel the 3 point or better limitation is restrictive enough without a short season, but the majority of the public did not want more than a week. The nonresident quota for region D will remain at 400 licenses to address the declining populations in region D herd units and the conversion of six hunt areas from general to limited quota in the Platte Valley. This will maintain hunter opportunity that is in line with the current mule deer resource.

ALBANY COUNTY PREDITOR BOARD SPECIAL PROJECT EVALUATING THE EFFECTS OF PREDATORS ON MULE DEER FAWN RECRUITMENT

Sheep Mountain Mule Deer Recruitment Project

Albany County Predatory Management District (ACPMMD), USDA/APHIS/Wildlife Services (WS'),
Wyoming Game and Fish Department (WGFD)

01/01/2013-12/31/14

The Sheep Mtn. Mule Deer Recruitment Project consists of a 3 yr. (01/01/2013- 12/31/2015) cooperative effort aimed at the removal of coyotes (*Canis latrans*) within Wyoming Hunt Areas 61, 74, 75, 76, 77 and adjacent lands. These removal efforts are aimed at increasing the viability of the mule deer (*Odocoileus hemionus*) herd that fawn in these areas. These areas lay Easterly adjacent to the Medicine Bow National Forest (USFS) and run generally North and South. This area is mainly used for cow/calf production, recreation, and grass cattle ranching. It is interspersed Private, Bureau of Land Management (BLM), United States Forest Service, and State of Wyoming lands. The goal of this project is to validate that coyote removal will prove beneficial to mule deer fawn recruitment.

The effort to remove coyotes from the hunt areas and adjacent lands began on 01/01/2013 and continues as the project moves towards the third year. Both ground and aerial hunting methods

will continue throughout the project time frame as funding, weather, recreational hunting use of lands, and time demanded by other WS' Albany County duties allow.

01/01/2013-12/31/2013 (1st year of 3)

A total of 89 coyotes within 18 different agreements were removed from the project area. When GPS waypoints of coyotes taken within the project area could be obtained, they were plotted as GPS points (squares) on the attached topographic map. Also, of the 89 coyotes, 24 were retrieved for comprehensive data collection.

Below is a series of operational, budget and coyote related to the data for the 1st year of the project time period (01/01/2013-12/31/2013).

30.9 hrs.	(\$6,573.00 ACPMD)*	Aerial hunting time only (fixed and rotor wing).
96.0 hrs.	(\$2,337.00 ACPMD, \$51.62 WS')*	Ground work time only.
26.0 hrs.	(\$1,342.12 WS')*	Administrative time only.
89		Coyotes removed from project area.
3		USDA/APHIS/WS personnel involved.

** (approximate costs incurred by ACPMD \$8,910.00 and WS' \$1,393.74)*

24 of 89 total (27%) coyotes taken verified for sampling and analysis below:

11	Adult male coyotes verified.
11	Adult female coyotes verified.*
1	Pup (female) coyote verified.
1	Pup (male) coyote verified.

** 1 adult female coyote showed evidence of 4 pups whelped.*

Stomach content occurrences on 24 verified coyotes.

10 Rodent	2 Empty	14 Pronghorn	3 Deer
-----------	---------	--------------	--------

1/1/2014-12/31/2014 (2nd year of 3)

A total of 116 coyotes and 1 den within 17 different agreements were removed from the project area. When GPS waypoints of coyotes taken within the project area could be obtained, they were plotted as GPS points (squares) on the attached topographic map. Also, of the 116 coyotes, 29 were retrieved for comprehensive data collection.

Below is a series of operational, budget and coyote related to the data for the 2nd year of the project time period (01/01/2014-12/31/2014).

54.0 hrs.	(\$13,446.00 ACPMD)*	Aerial hunting time only (fixed and rotor wing).
138.0 hrs.	(\$3,563.06 ACPMD, \$200.72 WS')*	Ground work time only.
39.0 hrs.	(\$1,957.02 WS')*	Administrative time only.
116/1 den		Coyotes removed from project area.
3		USDA/APHIS/WS personnel involved.

** (approximate costs incurred by ACPMD \$17,009.08 and WS' \$2,157.74)*

29 of 116 total (25%) coyotes taken verified for sampling and analysis below:

12	Adult male coyotes verified.*
13	Adult female coyotes verified.**
3	Pup (female) coyote verified.
1	Pup (male) coyote verified.

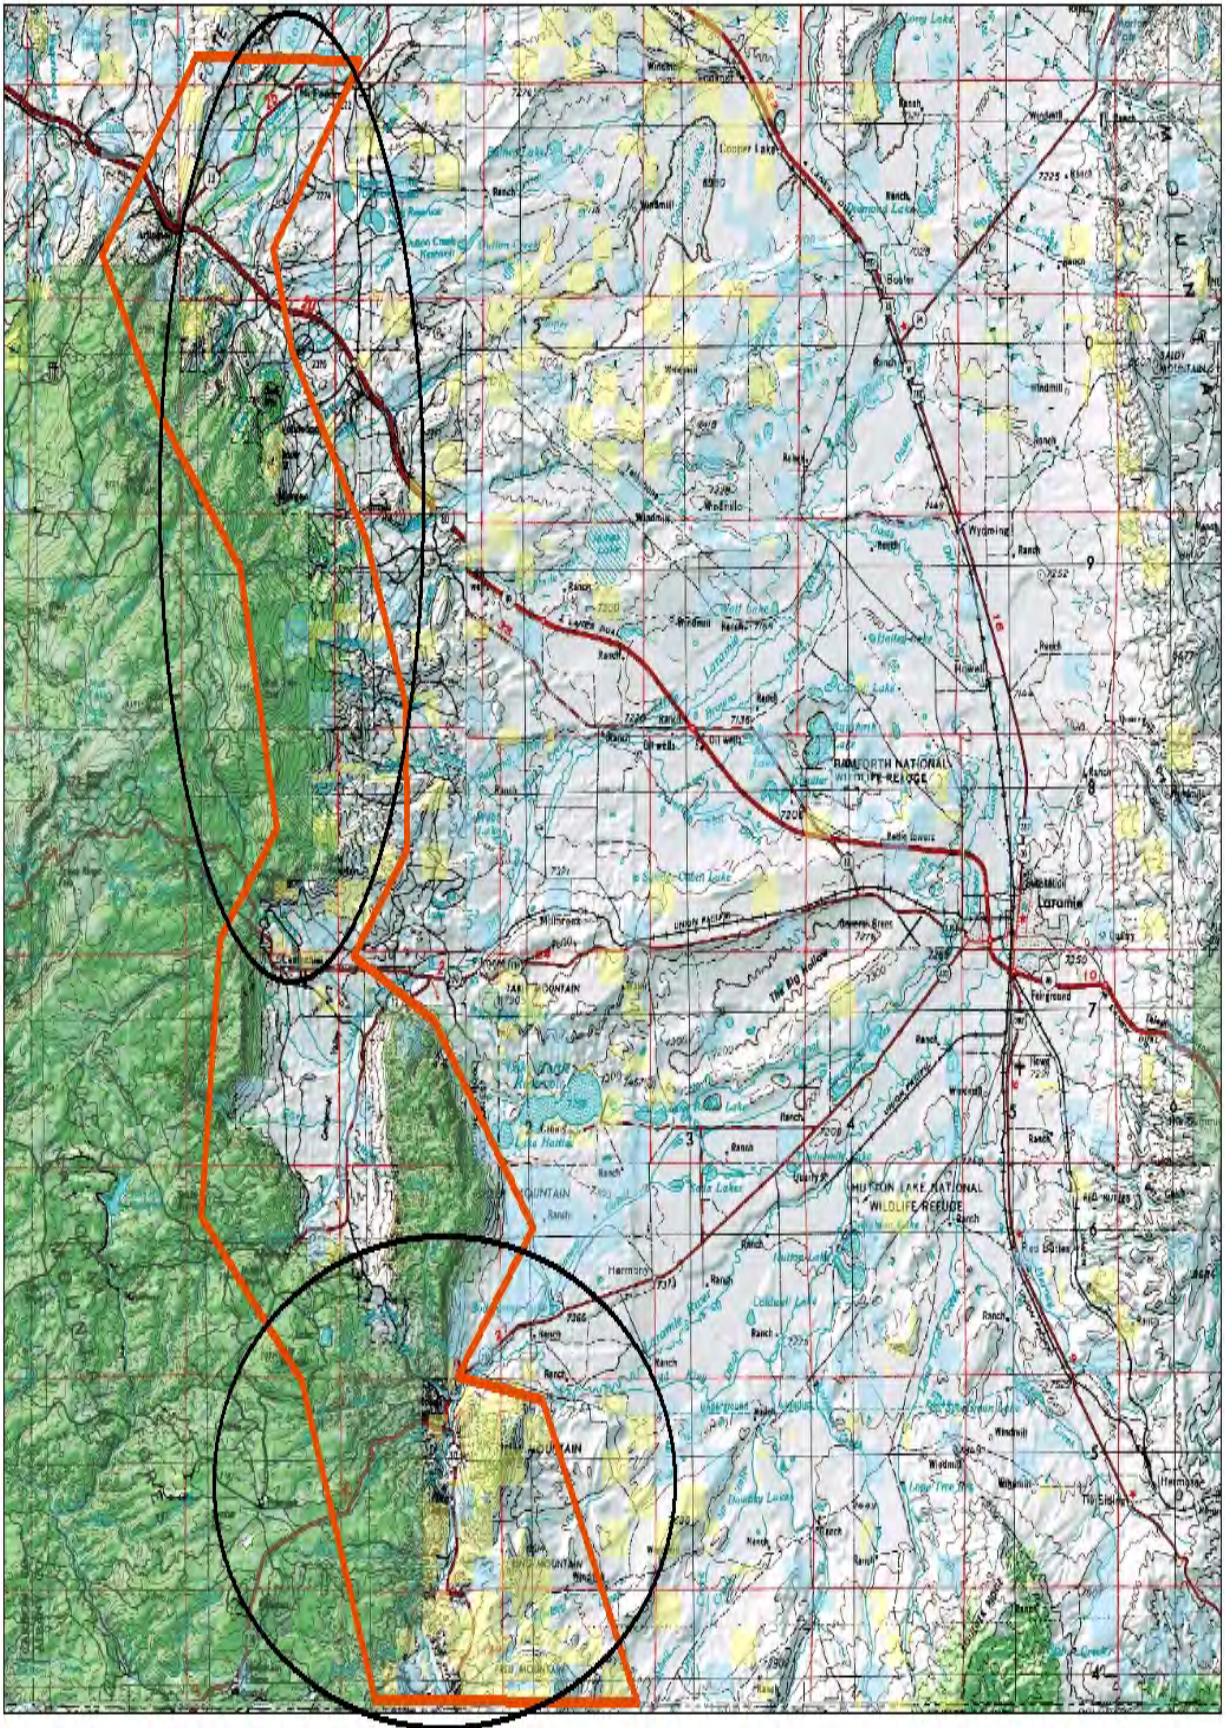

** 1 adult male exhibited signs of mange mite. **1 adult female showed evidence of 3 pups whelped. 1 adult female showed evidence of 6 pups whelped.*

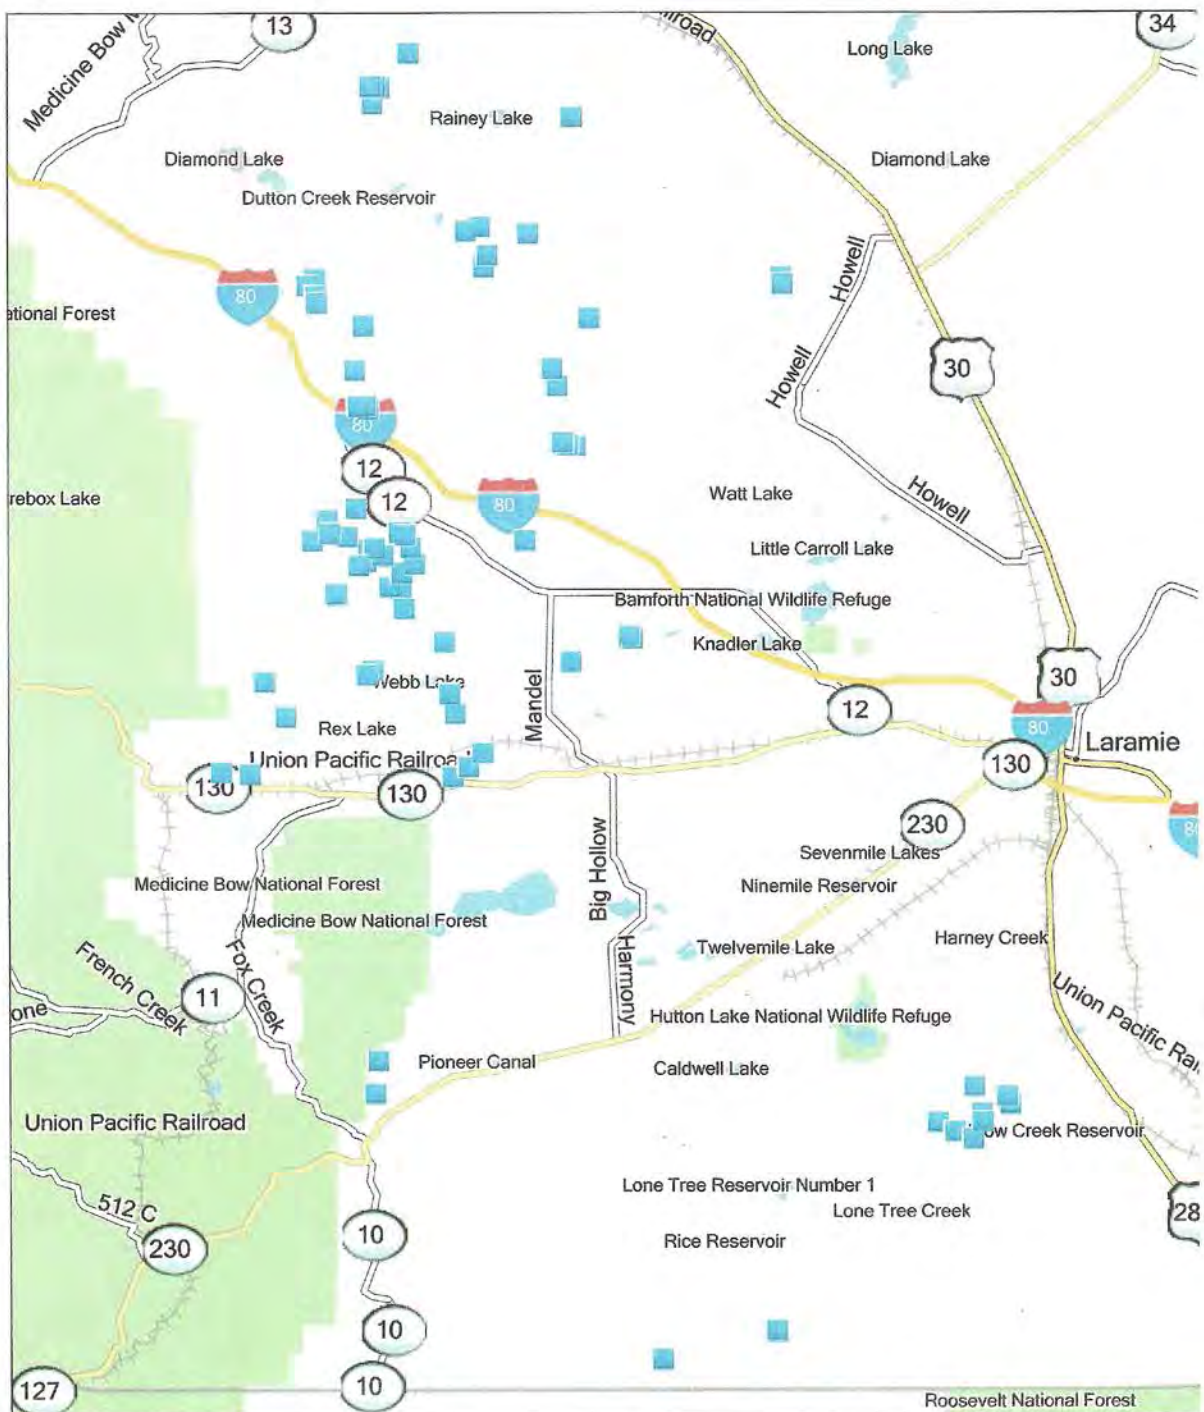

Stomach content occurrences on 29 verified coyotes.

15 Rodent 3 Empty 14 Pronghorn 4 Deer 2 Bird

Coyote Removal 10/2/13- 12/31/14'

My Collection

GARMIN.

The Sheep Mountain Herd Unit encompasses Hunt Areas 61, 74, 75, 76 and 77. Fawn ratios have varied over the last 10 years but they seem to be trending up. During the winters of 2007, 2009 and 2010 we experienced an increase in winter mortalities especially in younger age classes which may also have had an effect on fawn recruitment. Severe drought persisted in the spring of 2012 through the spring of 2013 and may have led to the decrease in the 2013 fawn ratio. Mild winter, above average spring moisture, and 2 years of coyote removal on parturition range has led to the highest fawn ratio in over a decade for this herd in 2014.

As stated on the cover sheet, ground and aerial activities will continue until 12/31/2015 as time and conditions permit. Very few mule deer were observed during the 1st years' work on the project. It appeared that the weather conditions during the last few years are impacting the population. Quite a few mule deer were observed during the 2nd years' work in the same project areas as the previous year. It is our hope that by removing coyotes in this project area coupled with the increase in moisture, the mule deer population will be able to increase or sustain its numbers over the next year/years.

Please feel free to contact me if there are any questions or concerns.

Sincerely,

Craig Acres

Staff Biologist USDA/APHIS/WS'

APENDIX B
SHEEP MOUNTAIN MULE DEER HERD UNIT OBJECTIVE REVIEW

SHEEP MOUNTAIN MULE DEER HERD UNIT AND OBJECTIVE REVIEW

Prepared by: Lee Knox, Laramie Senior Wildlife Biologist

The herd unit concept is based on distinct populations and minimal interchange ($\leq 10\%$) with neighboring populations. The Sheep Mountain Mule Deer Herd Unit (SMMDHU) occupies an estimated 2,500 square miles in southeastern Wyoming, ranging from the city of Cheyenne west to the Snowy Range divide, and from the Colorado/Wyoming state line north to Highway 287/30 and Interstate 80 (Figure 1). The herd unit encompasses hunt areas 61, 74, 75, 76 and 77. Landownership varies from private lands with limited public access to public lands easily accessible. The current Postseason Population Management Objective was last reviewed in 1987 when it was increased from 10,000 to 15,000 mule deer. The herd unit is managed under recreational guidelines which prescribe to maintain a ratio of 20 to 29 bucks:100 does.

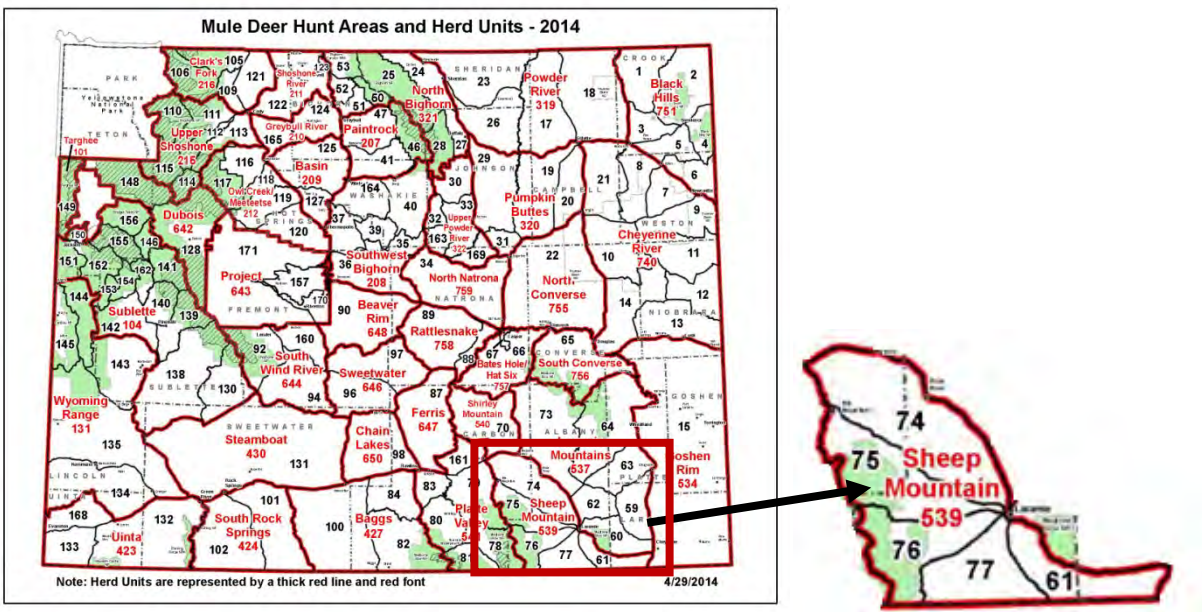

Figure 1. 2014 Wyoming mule deer herd units. The Sheep Mountain Mule Deer Herd Unit is highlighted.

POPULATION OBJECTIVE REVIEW

The postseason population objective for this herd unit is currently 15,000 mule deer. The 2014 post-season population estimate was approximately 5,600 mule deer with the population stabilizing after a decline from 7,500 mule deer in 2009 (Figure 2). The postseason population objective is based upon both biological and social factors, including, but not limited to: winter range carrying capacity, hunter needs, landowner needs and tolerance, land status, and competition with other wild and domestic animals. The postseason population estimate is determined by modeling herd dynamics using harvest data and preseason herd classification data.

The SMMDHU population model has been further refined by addition of both adult female and juvenile survival data from research projects conducted in neighboring herds.

Figure 2. Population estimates and objective for the Sheep Mountain Mule Deer Herd Unit, 1993-2014.

CURRENT HERD UNIT MANAGEMENT STRATEGIES

Hunt areas 61, 74, 75, 76, and 77 are managed through a general season structure and recreational guidelines. Although landownership and habitats differ between hunt areas, the same season structure has been maintained due to the overall population size being below objective which requires a conservative management strategy across all hunt areas in the herd unit.

LANDOWNER AND PUBLIC INVOLVMENT

Surveys were mailed to 107 landowners that owned a minimum of 640 acres in the SMMDHU. Of the 107 letters mailed, 24 completed surveys were returned. At the postseason public meetings in Saratoga, Wheatland, Torrington, Laramie, and Cheyenne, questionnaires were provided to the public, similar to those mailed to the landowners. Only one questionnaire was returned.

Overall, 63% of the landowners that responded were dissatisfied with the current mule deer population (Figure 3). When asked why, 65% of dissatisfied landowners responded that there were too few mule deer, while 5% responded that there were too many mule deer (Figure 4).

Figure 3. Current landowner satisfaction with the SMMDHU population.

Figure 4. Landowner response as to why they were satisfied/dissatisfied. .

Sixty-seven percent of the landowners surveyed believed that the current population objective of 15,000 mule deer was correct (Figure 5). Only 16% believed it should be lowered. Historically, the population was estimated to be near 15,000 mule deer for only a short period in the early 1990s. Using the current model, the population estimate has not been over 8,000 mule deer at any time during the past 20 years (Figure 2).

Figure 5. Landowner opinion of the current population objective of 15,000 mule deer.

Harvest has been on a steady decline from 984 mule deer in 2004 to 197 mule deer in 2013. The 2014 harvest saw a slight increase to 290 mule deer (Figure 6). Hunter success has declined precipitously since 2004 (Figure 7). Overall hunter numbers have declined by more than 1,000 over the last decade, indicating low satisfaction with the SMMDHU (Figure 6).

Figure 6. Number of hunters and mule deer harvested in the SMMDHU from 2003-2014.

Figure 7. Hunter success and effort, measured as days per harvest, from 2003 to 2014.

RECOMMENDATION

Through the Wyoming Mule Deer Initiative process, public meetins, and landowner meetings, the current population objective and whether it should be lowered to an achievable level has been discussed with the public. The current population objective of 15,000 mule deer is unrealistic considering the current population model estimates and current habitat conditions. Public meetings were held in Wheatland, Laramie, Cheyenne, Saratoga, and Casper to propose a new objective of 10,000 mule deer. A total of 80 members of the public attended the meetings. We received five surveys back, all in favor of reducing the current population objective from 15,000 to 10,000 mule deer. A postseason population objective of 10,000 deer may still be difficult to obtain in five years, especially considering past population trends, but it is more palatable to the landowners and the public. If after five years, the population objective is not attained, this objective should be reviewed again.

Appendix A

List of Landowners Contacted

March 13, 2015

Dear Landowner,

The Wyoming Game and Fish Department (Department) is seeking your assistance in the future management of big game wildlife in your area. During the spring of 2015, the Department will review the herd unit management objectives for several big game herd units including the Sheep Mountain Mule Deer Herd Unit. Enclosed in this letter you will find a short survey for the herd unit your property is located within and postage-paid return envelope. Please complete the survey questions, provide additional comments if you desire, and mail the survey in the enclosed return envelope.

The herd unit management objective is the “goal” which the Department manages big game wildlife towards. For most big game herd units in Wyoming, the Department manages big game wildlife towards a numeric management objective, usually identified as a postseason population estimate.

Many of Wyoming’s big game wildlife rely on habitat located on private lands. Therefore, landowner opinions on herd unit management objectives are important to Department. The comments we receive from your completed surveys will be used in part to formulate Department recommendations for the future herd unit management objectives. Changes in the herd unit management objective could result in increasing harvest opportunities to decrease the number of big game animals, or conversely, changes could result in reducing harvest opportunities in order to increase the number of big game animals. For planning purposes, the Department would like to identify management objectives which are considered biologically achievable within the next five years.

Thank you for taking the time to share your thoughts and opinions with us. If you have any questions please contact Lee Knox (307) 760-7348. We look forward to receiving your survey and working with you on the future management of Wyoming’s Wildlife.

Sincerely,

Lee Knox
Laramie Wildlife Biologist

Surveys and Tallies of Survey responses

Sheep Mountain Mule Deer Herd Unit Objective Review

1. How satisfied are you with the current Sheep Mountain mule deer population (please circle):

Very Satisfied Somewhat Satisfied Somewhat Dissatisfied Very Dissatisfied

1. Please indicate why you selected the response you did for question 1.

- ☐ There are too many mule deer in the population
- ☐ There is the right amount of mule deer in the population
- ☐ There are too few mule deer in the population
- ☐ Other _____

2. Do you think the current post-season population objective of 15,000 mule deer is:

3. Too high (we would bring it down to a biologically achievable number)

4. Too low (increase it even though it would not be achievable)

5. About right (continue to use the current objective even though the population has not been within 20% of the objective in 20 years)

If you have additional comments, please share them in the space below:

If, in the future, you would like to be contacted through email please provide your email address below.

THANK YOU for your participation!

24 responses

Summary

How satisfied are you with the current Sheep Mountain mule deer population

Very Satisfied	1	4.2%
Somewhat Satisfied	6	25%
Somewhat Dissatisfied	7	29.2%
Very Dissatisfied	5	20.8%

Please Indicate why you selected the response you did for question 1

There are too many mule deer in the population	1	4.2%
There is the right amount of mule deer in the population	4	16.7%
There are too few mule deer in the population	13	54.2%
Other	2	8.3%

Do you think the current post-season population objective of 15,000 mule deer

is:

Too high	3	12.5%
Too low	3	12.5%
About right	12	50%

Additional comments

We don't own any ground in this management area.

Please don't waste your postage and printing costs- Our opinion as landowners matter not on what you do.

I know very little about the mule deer population on Sheep Mountain. My guess is that your management area extends to the Rock Creek valley and that is why you sent this to me. As for the McFadden area where we live, there is nothing to talk about. The whitetail deer have pushed all the mule deer out of here. We see a small herd at Rock River.

Not familiar enough with deer in targeted area to make a valid opinion. Earle Steward
1917 S. Second Ave Cheyenne, WY 82007

1. The deer have not recovered from wasting disease and slaughter by Colorado Game dept. I used to have hundreds here thru the winter. Now I'm fortunate if I see 5 or 6. 2. This area should return to "restricted" area (6)-- drawing only. Since becoming a "general area" hunters are driving me crazy!! I can hardly get any work done and I dare not leave from Oct to Feb. Trespassing, gates open, fences cut, pastures smashed, wounded animals left to die, property damage or missing. We are too close to major population areas to allow general area hunting! General area=open to all (to many!!!) -Robert Green

I attended a couple of your meetings. You talk about habitation private land being important, but you have no private land habitat program. In fact i read and heard a negative attitude about working with private landowners. You talk about working with USFS but openly express how hopeless it is to more USFS. So- I wonder if you are in there to win or just look good losing.

We have noticed an increase in the number of deer during the last two years. The Remount Ranch is only 4000 acres so I don't know if that reflects the deer population for

all of our area. We don't allow hunting on the property and that may be the reason for the increase.

This past year is the most deer i have seen on our land but we don't think it to much as of right now.

Lets be realistic about the numbers. 15000 is too high, unachievable and not a number that could be maintained. Our elk are gone and the deer are returning. I am more pleased to share the land with the deer than the elk.

Have a reasonable and achievable objective to meet, and continue to grow herd.

They are gone.... NONE. As a species they probably wont survive, wouldn't that be sad! They consume a lot of our grass. Thank you for your efforts.

In the 20 years we have owned the ranch, I have not heard any mountain on or near our property referred to as Shirley Mountain, so I guess I can't answer any questions about the Shirley Mountain mule deer population. If it helps you, in the 20 years we have owned the ranch we have only taken two mule deer bucks, and there appears to be fewer deer today. Berthel Land & Livestock 307-630-5453

We are in the middle of a 30 year dry cycle. How much hast that affected the population? Predators need to be kept in check. To many elk competing for habitat.

Hi Lee this is Gary Browning love to help Game and Fish, and mule deer. Call at 307-760-0966 or stop by 120 Hart Rd and we can visit.

Mule deer population on Chimney Rock Ranch is very low- Bruce Lewis

Make all snowy range areas limited quota's for mule deer! NO general license to close to urban populations.

We have experienced a subjective decrease in mule deer over the last 25 years on our meadow lands. I would like to see a few more deer and a few less antelope. We do have an increase in whitetail.

Sheep Mountain Mule Deer Herd Unit Objective Review

1. Do you think the current post-season population objective of 15,000 mule deer is:

- ☐ Too high (we would bring it down to a biologically achievable number)
- ☐ Too low (increase it even though it would not be achievable)
- ☐ About right (continue to use the current objective even though the population has not been within 20% of the objective in 20 years)

If you have additional comments, please share them in the space below:

If, in the future, you would like to be contacted through email please provide your email address below.

Sheep Mountain Mule Deer Herd Unit Objective Review

1. How satisfied are you with the current Sheep Mountain mule deer population:

- ☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☒ Very Dissatisfied

2. Please indicate why you selected the response you did for question 1.

- ☐ There are too many animals in the population
☐ There is the right amount of animals in the population
☒ There are too few animals in the population
☐ Other _____

3. What do you think about the current post-season population objective of 15,000 (12,000-18,000) mule deer?

- ☐ Current Herd Objective Needs to Increase
☒ Current Herd Objective Needs to Decrease
☐ Current Herd Objective is Acceptable

4. If you have additional comments, please share them in the space below:

If, in the future, you would like to be contacted through email please provide your email address below.

THANK YOU for your participation!

Sheep Mountain Mule Deer Herd Unit Objective Review Sportsman's Survey

We propose to decrease the management objective from 15,000 to 10,000 mule deer postseason.
(Current population estimate is ~5,600)

___ I support this proposal

 I do not support this proposal

☒ I support this proposal

☐ I do not support this proposal

Comments:

It is so far below objective lowering it to 10,000 is OK.

Make the RMEF projects/money good for all species - elk, mule deer, moose, etc.

Not just elk.

If, in the future, you would like to be contacted through email please provide your email address below.

Comments:

Why? What's the point of the objective change? If the
highest the population has been (since 1993) is 8k, why would the
objective change be needed?

2015 Hunting Seasons

Hunt Area	Type	Dates of Seasons		Quota	License	Limitations
		Opens	Closes			
70		Oct. 15	Oct. 21		General	Antlered mule deer three (3) points or more on either antler or any white-tailed deer
	6	Oct. 15	Nov. 30	25	Limited quota	Doe or fawn valid on private land

Nonresident Region D Quota: 400

Hunt Area	Type	Quota change from 2014
Herd Unit Total		None

Management Evaluation

Current Management Objective: 10,000 (8,000-12,000)

Management Strategy: Recreational

2014 Postseason Population Estimate: 4,900

2015 Proposed Postseason Population Estimate: 5,000

2014 Hunter Satisfaction: 51% Satisfied, 22% Neutral, 27% Dissatisfied

Mule deer in the Shirley Mountain herd unit are managed toward a numeric objective of 10,000. The population was estimated using a spreadsheet model developed in 2012 and update in 2014. The herd is managed for recreational opportunity. The objective was reviewed in 2015 and the final proposal will be reviewed by the Game and Fish Commission in July of 2015.

Herd Unit Issues

The Shirley Mountain herd unit is comprised of a mixture of habitat and landownership types. Hunter access to public lands containing mule deer habitat is considered good. Small groups of mule deer are considered nuisances and create damage in a localized area on the west side of Shirley Mountain, along Lost and Sage Creeks. Trends in mule deer numbers are in decline while interest from both residents and nonresidents in hunting in this herd unit have increased over the past 5 years. Expansion of wind farms in the eastern half of this herd unit is eminent.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and

preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on mule deer. Mild fall temperatures and lack of persistent snows allowed for mule deer to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Shirley Mountain herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunk brush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

2014 Postseason classifications were conducted from the ground in late November. A less than adequate sample size (n=306) was 25% lower than the 2013 sample size. Yearling buck ratios increased by 1 buck to 12/100 does. However, a significant increase in the yearling buck ratios usually observed after the implementation of a 3-points or more on either antler limitation has not been realized in this herd unit. The adult buck ratio increased 28% in 2014 to 18/100 does. The overall buck ratios increased from 26/100 does in 2013 to 30/100 does in 2014. This increase was attributed to reducing the nonresident Region D quota in 2014.

Fawn ratios increased from 42/100 does in 2013, which was the lowest fawn ratio observed during the past 25 years, to 50/100 does in 2014. This increase was attributed to mild winter conditions experienced by pregnant does and timely spring and summer precipitation which resulted in improved nutrition for lactating does. However, the observed fawn ratio was below the trend for this herd unit and did not result in an increased population estimate for 2014.

Harvest Data

Overall, harvest and satisfaction rates increased in 2014. This marked the second year of the 3-points or more on either antler limitation in this herd unit. The antler point restriction was implemented as an additional protection specifically for yearling bucks. General season lengths had already been incrementally reduced to the current 7-day season during previous years to protect overall buck numbers. The final 2014 WGFD deer harvest survey report indicated 557 active general licensed hunters' harvested 207 mule deer for an overall success rate of 37%. General season buck harvest increased 18% and hunter numbers increased 10%, as compared with the 2013 hunting season statistics. The percentage of hunters with harvest survey satisfaction ratings of satisfied, or very satisfied, increased 10% to 51% in 2014.

Population

In 2014, we selected to use the TSJ,CA model. Although the TSJ,CA model had the highest AICc score at 142, when compared with the CJ,CA, and SCJ, SCA model scores, (95 and 91 respectively), it allowed for better alignment of the predicted buck ratios with the observed buck ratios. It also produced the lowest and most biologically plausible postseason population estimate for 2014. The TSJ,CA models tend to simulate mule deer population dynamics better than the other models because fawn survival rates are allowed to fluctuate on an annual basis with great variability, similar to survival rates that have been documented in numerous investigations (Andy Holland, Colorado Division of Parks & Wildlife, pers. comm.). We also incorporated 3 abundance estimates into this model (Strickland, et. al 1994).

We rated this model as poor, and not biologically defensible. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model, and primarily due to less than adequate sample sizes for postseason classification counts (Morrison 2012).

This herd unit is considered to contain significantly less mule than the spreadsheet models estimate. Given the openness of the landscape, and well defined herd unit boundaries, we consider the observed harvest rates and classification sample sizes were not representative of a population estimated at this magnitude. The declining trend depicted in the spreadsheet model's population estimates does appear to be representative of the observed mule deer abundance in this herd unit. Without other information such as a recent independent population estimate or long-term survival data to incorporate into the models, accuracy of estimates will continue to be unknown.

Management Summary

The 2015 hunting season included a 7-day General season for antlered mule deer, 3 points or more on either antler, or any white-tailed deer hunting. The point restriction continued to provide protection for yearling buck mule deer. Type 6, private land doe or fawn licenses were prescribed to reduce damage and nuisance deer issues in the Lost and Sage Creek areas.

The Region D nonresident quota was retained at 400 licenses to align hunter opportunity with the current mule deer resource. This will also improve hunter satisfaction for both nonresidents and resident hunters alike.

Management Evaluation

Current Management Objective: 16,000 (12,800 – 19,200)

Management Strategy: Recreational

2014 Postseason Population Estimate: 11,000

2015 Proposed Postseason Population Estimate: 11,000

2014 Hunter Satisfaction: 62% Satisfied, 21% Neutral, 17% Dissatisfied

Mule deer in the Platte Valley herd unit are managed toward a numeric objective of 16,000. The population was estimated using a spreadsheet model developed in 2012 and updated in 2014. The herd is managed for recreation opportunity. The objective was reviewed in 2014 and reduced to a postseason population estimate of 16,000 mule deer (Appendix A).

Herd Unit Issues

Fieldwork for several Platte Valley Habitat Partnership projects was initiated during this past year in this herd unit. The University of Wyoming Cooperative Unit continued to analyze data from the Platte Valley sightability survey evaluation and telemetry projects. A meeting was held in February, in Saratoga, to update the public about Platte Valley Mule Deer Mule Deer Plan accomplishments.

Efforts to reduce predators of mule deer in the Platte Valley were continued during this period. Carbon County Predator Management District completed the second year of a 3-year coyote removal project.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit. No significant prolonged periods of extreme heat or cold temperatures were observed or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on mule deer. Mild fall temperatures and lack of persistent snows allowed for mule deer to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been over utilized. For specific meteorological information for the Platte Valley herd unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

Habitat conditions improved in 2014 with an increase in amounts of precipitation received and the timeliness of when it was received. Precipitation received in April and May resulted in excellent growth of cool season grasses and forbs, and above average leader growth on preferred key shrubs. 2012 has been recognized as one of the worst droughts on record, and annual growth of key forages monitored finally returned to levels seen prior to 2012. Utilization rates of key winter range shrubs documented in the spring of 2014 was within acceptable use limits in most areas. Shrub habitats receiving treatments thru prescribed fire or mowing continue to outperform areas not receiving treatment from an overall production standpoint.

The limited number of habitat transects that have been established throughout the Laramie Region have not provided sufficient data to make reliable assumptions of habitat quantity or quality and consequently heavily influence population management for any particular big game specie. The vast majority of shrub habitats are still in need of treatment to improve nutritive content and overall leader production potential.

Shrub communities within the Laramie Region that are annually assessed by game wardens, wildlife biologists, and terrestrial habitat biologists, include: true mountain mahogany, antelope bitterbrush, skunk brush sumac, big sagebrush, and four-wing saltbush. A majority of these transects were established approximately 12–13 years ago. Transects were established for several different reasons, including: measuring habitat response prior to or following treatments (i.e. prescribed fire, wildfire, mowing), concern over historic or current domestic livestock or wild ungulate utilization levels, selection of, “Representative habitats,” utilized by wildlife on identified winter ranges, and to compare present results with historic data sets.

Field Data

The 2013 Platte Valley Herd Unit postseason classification ratios were 36 bucks and 63 fawns/100 does; based on an adequate sample of 1,767 mule deer. The buck ratio increased 11% in 2014. This increase was attributed to the combination of both a conservative limited quota hunting season and greater over winter survival than in recent years. The observed fawn ratio at 63 fawns/100 does was 17% greater than the previous year. A mild winter and timely precipitation contributed to providing improved habitat conditions and increased nutrition for mule deer.

Harvest Data

2014 marked the second year for limited quota hunting in the Platte Valley herd unit. Each hunt area was prescribed a license quota specific to that hunt area. The same quotas from 2013 were retained in 2014 as they had permitted harvest success to attain the PVMDI Mule Deer Plan goal of at least 40%. A total of 934 active licensed hunters harvested 515 bucks and 13 does. Overall harvest success increased from 44% in 2013 to 57% in 2014 and buck harvest increased 11% to 55%. Similarly to the 2013 harvest rate, the 2014 harvest rate was attributed to the increased survival rates, a season length of 14-days, and perhaps most importantly, a reasonable alignment of hunter numbers with the current mule deer resource. The increased harvest success rate translated into an increase in the number hunters who selected a harvest survey satisfaction rating of satisfied, or very satisfied. Hunter satisfaction increased from 57% in 2013, to 62% in 2014.

Harvest rates of yearling bucks increased in 2014. Yearling bucks made up 26% of the buck harvest. This was an increase of 14% over 2013. Field checked harvest data from previous years indicated on average, greater than 25% of the buck harvest consisted of yearling bucks. The increased number of yearling bucks observed in 2014 harvest was attributed to more yearlings being conspicuously available due to increased survival for the 2013 fawn cohort due to the mild over-winter conditions.

Population

We continued the use of the TSJ,CA spreadsheet model in 2014. This model provided the balance of allowing juvenile survival rates to be optimized for alignment with observed population dynamics, while maintaining a constant survival rate for adult mule deer in model simulations. The TSJ,CA model also offered the best AICc score of the suite of spreadsheet models. TSJ,CA model aligned very well with abundance estimates for this herd unit and corroborated with the observations from field managers and the public.

We rated this model as fair, and biologically defensible in our evaluation. This rating was based on criteria identified in the user's guide for the WGFD spreadsheet model (Morrison 2012).

Management Summary

In 2015, the limited quota licenses numbers and season length will remain the same as in 2014. This hunting season framework will continue to support the goals identified in the Platte Valley Mule Deer Plan. Overall, hunters and other stakeholders appear to be very satisfied with the improvements we have made in mule deer management in this herd unit. Predator management and habitat improvement projects will also continue in 2015 as means to improve and sustain mule deer and their habitat in the Platte Valley herd unit. In 2016, we will conduct an in depth collaborative review and analysis of the Platte Valley Mule Deer Plan, including the limited quota hunting season framework.

2014 PLATTE VALLEY MULE DEER HERD UNIT AND POPULATION OBJECTIVE REVIEW

Prepared by: Will Schultz, Saratoga Wildlife Biologist

The Platte Valley mule deer herd unit is located in south central Wyoming and consists of deer Hunt Areas 78, 79, 80, 81, 83, and 161 (Figure 1). Hunt Areas 78 and 79 are located on the west slope of the Snowy Range, and Hunt Areas 80 and 81 are located on the east slope of the Sierra Madre Range, in the Medicine Bow Mountains. Hunt Areas 83 and 161 are located immediately adjacent in the northern portion of the herd unit and contain drier and less productive habitats. Hunt Areas 83 and 161 are included in the herd unit because mule deer that summer in high elevation mountain habitat in the southern portion of the herd unit migrate to winter ranges in these hunt areas during winter (Ward et al. 1976).

Figure 1. A map of the Platte Valley mule deer herd unit and hunt areas located in south central Wyoming.

The Platte Valley herd unit contains 7,045 km² of delineated seasonal mule deer range. Elevations range from 1,951 m along the North Platte River to just over 3,658 m at Medicine Bow Peak. Habitat types include alpine meadows, subalpine and montane forests, mountain shrub, sagebrush-grasslands, grasslands, cottonwood riparian, and agricultural croplands. Landownership in the herd unit is a mixture consisting of 41% private, 28% US Forest Service, 25% Bureau of Land Management, 5% State Land and Investment Board, and 1% Wyoming Game and Fish Commission.

POPULATION OBJECTIVE REVIEW

Wyoming Game and Fish Department (WGFD) uses postseason population objectives as a guide for mule deer management at the herd unit level. The postseason population objective is the desired number of mule deer remaining in the herd unit after the annual hunting season has been completed. Generally, if the population estimate is above the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will increase harvest and reduce the number of mule deer toward the population objective. Conversely, if the population estimate is below the population objective, WGFD will propose changes to the herd unit's next hunting seasons which will decrease harvest and increase the number of mule deer toward the population objective.

An actual count of all mule deer in a herd unit would be, for all practical purposes, impossible to complete. Therefore, WGFD develops herd unit population estimates using a computer-based population model. Data collected annually through hunter-harvest surveys and postseason mule deer sex and age classification surveys are incorporated into the population models. The population estimate produced by the computer-based population model is used to determine where the herd unit's mule deer population is at in relation to the established population objective.

Annual population estimates for the Platte Valley herd unit are currently produced using a computer-based, spreadsheet population model (Morrison 2012). Hunter-harvest surveys and postseason mule deer sex and age classification survey sample sizes have been adequate for producing estimates with acceptable 80% confidence intervals. Retrospective comparisons of population estimates produced by the spreadsheet model are lower than those previously reported using the POP-II population model. Generally, the spreadsheet model's estimates are considered more accurate than the previous POP-II population model. Additionally, WGFD has conducted 3 mule deer sightability surveys (Unsworth et. al.1999) in this herd unit. Abundance estimates from these sightability surveys were incorporated into the spreadsheet model to improve the population estimate's accuracy.

Postseason mule deer population objectives for the Platte Valley herd unit have been adopted and subsequently changed following periodic reviews of both biological and social considerations. These considerations have included, but were not limited to: changes in the herd unit boundary delineation, changes in quantity and quality of habitat, sportsmen desires, and landowner desires/tolerance.

A postseason population objective of 20,000 mule deer was first established for the Platte Valley herd unit in the late 1970s. In 1982, the population objective was decreased to 15,000 mule deer due to the removal of the South Ferris area (Hunt Area 86) from the herd unit. It was returned to 20,000 again in 1987 because stakeholders desired seeing the population maintained at what was estimated at that time to be approximately 20,000 mule deer. The population objective has been retained at 20,000 since 1987.

The 2013 postseason population estimate was 8,700 mule deer. Since 2004, the annual population estimates have declined precipitously in trend (Figure 2). Although there are many factors believed to be contributing cumulatively to the decline, the direct and indirect impacts from severe winters and drought are considered to be the most significant factors.

Figure 2. 1993-2013 Platte Valley herd unit postseason mule deer population estimates, Wyoming.

CURRENT MANAGEMENT STRATEGIES BY HUNT AREA

All hunt areas in the Platte Valley herd unit are managed under the recreational management strategy. This strategy directs WGFD to manage harvest opportunity to maintain 20-29 bucks/100 does in the herd unit postseason.

In 2012, WGFD collaboratively developed the Platte Valley Mule Deer Plan (WGFD 2012) and subsequently began to implement additional strategies identified in this plan to improve the quality of the hunting experience in this herd unit. These strategies included: a.) changing

hunting season structure from traditional general seasons to limited quota seasons; b.) set a goal to achieve a buck harvest success rate of 40%; c.) set a goal of at least 20% of field-checked harvested bucks meeting an antler spread of 24" or more; and d.) set a goal of at least 60% of the harvest survey respondents replying they were "satisfied" or "very satisfied" with their hunting experience. These additional management strategies will be reviewed collaboratively in 2016 to determine if they have improved the quality of the hunt to a satisfactory level, and whether or not to continue their use.

RECOMMENDED HERD UNIT OBJECTIVE AND MANAGEMENT STRATEGIES BY HUNT AREA

WGFD recommends the population objective for the Platte Valley herd unit be reduced to a level which is presently considered both biologically achievable, and sustainable. We recommend reducing the postseason population objective from 20,000 mule deer to 16,000 mule deer. We also recommend maintaining the recreational management strategy for all hunt areas in the Platte Valley herd unit.

Two years ago, WGFD began the long overdue task of reviewing objectives for all big game herd units in Wyoming, to be completed over the course of the next 5-years. At the root of this effort was a genuine need to update the objectives with goals which were both biologically achievable, and sustainable. Much has changed since many of these herd unit objectives were last reviewed. Most notably, changes in the ability of the habitat to sustain the population levels which had been previously met in many herd units.

An indicator of the habitat's inability to continue to support mule deer population levels previously observed in many herd units has been reduced recruitment rates for mule deer. A declining trend in recruitment has been documented in almost every herd unit in Wyoming, as well as in many areas across the west. This declining trend has been primarily attributed to changes in the ability of habitat to provide the specific forage, cover, and security required by mule deer. Changes in seral stages of vegetative communities to less productive stages, severe drought which has reduced annual forage production, and the conversion of habitat to residential and energy development, all have cumulatively reduced habitat for mule deer.

While the recommended population objective is 20% less than the current objective of 20,000 mule deer, 16,000 mule deer is 46% greater than the current population estimate of 8,700 mule deer. In an effort to halt the mule deer decline and reverse the population trend, WGFD has recently implemented several efforts which should enhance the ability of the Platte Valley herd unit to sustain mule deer. WGFD has begun to implement several landscape scale habitat improvement projects under the Platte Valley Habitat Partnership (WGFD 2013). WGFD has supported efforts to reduce large carnivore and predator populations in this herd unit in an attempt to increase mule deer recruitment. While the benefits of these and other efforts may not be immediately realized, we believe they will assist in the recovery of mule deer.

LANDOWNER, AGENCY, AND PUBLIC INVOLVEMENT

WGFD made a concerted effort to provide stakeholders with an opportunity to be involved in the review of the Platte Valley mule deer herd unit population objective, and to provide comment on the recommendations. Mule deer are a species of great concern for many of the stakeholders who participated in the review process. There was almost a unanimous desire by all stakeholders during this process to see the current number of mule deer (estimate = 8,700) increased. However, opinions varied on what population objective should be recommended for a future management goal.

Landowner Involvement

In February of 2014, a letter describing objective review process and a survey were sent to all landowners (n=123) who owned at least 160 acres in the Platte Valley herd unit (ATTACHMENT A). We received completed surveys from 36 landowners; for a return rate of 29% (ATTACHMENT B). Seventy-eight percent (78%) of the landowners indicated they thought the current population objective was “About Right.” Nine percent (9%) of the landowners indicated the population objective was, “Too High,” (Figure 3.)

Figure 3. Platte Valley herd unit landowner survey responses to the question, “Do you think the population objective of 20,000 mule deer is:”

In May of 2014, WGFD sent a postcard to these same landowners describing the recommendation to reduce the population objective from 20,000 mule deer to 16,000 mule deer (ATTACHMENT C). The postcard included an invitation to the landowners to attend upcoming objective recommendation meetings. The postcard also listed an email address where landowners could send their comments electronically. No comments were received from the landowners.

Agency Involvement

In May of 2014, WGFD met with representatives from the US Forest Service (Wendy Haas - Medicine Bow/Routt National Forest); Bureau of Land Management (Heath Cline - Rawlins Field Office); USDA/Natural Resource Conservation Service (Mark Shirley - Saratoga District); and the Saratoga, Encampment, Rawlins Conservation District (Jack Berger and Joe Parsons). WGFD presented a review of the Platte Valley herd unit population objective and the

recommendation. This discussion lasted approximately 2 hours. Agency personnel appeared to be supportive of the recommendation.

A letter was received from the Carbon County Predator Management District Board expressing they did not support the recommendation to reduce the population objective from 20,000 mule deer to 16,000 mule deer (ATTACHMENT D).

Public Involvement

In March of 2014, population objective review meetings were held in conjunction with season-setting public information gathering meetings in Cheyenne, Laramie, and Saratoga. Meeting attendees were asked to fill out sportsperson surveys regarding their attitudes towards current mule deer numbers and the current population objective (ATTACHMENT E). A total of 110 people attended these meetings and we received 21 completed surveys, for a return rate of 19% (ATTACHMENT F). Sixty-seven percent (67%) of the survey respondents indicated they thought the current population objective was “About Right,” and 14% thought the population objective was, “Too High,” (Figure 4.)

Figure 4. Platte Valley herd unit public objective review meeting attendee survey responses to the question, “Do you think the population objective of 20,000 mule deer is:”

In May of 2014, population objective recommendation meetings were held in Cheyenne, Laramie, Saratoga, and Wheatland. Meeting attendees were asked to fill out surveys indicating whether or not they supported the proposed population objective recommendation. A total of 21 people attended these 4 meetings and we received 8 completed surveys; for a return rate of 38% (ATTACHMENT G). Sixty-three percent (63%) of the survey respondents indicated they supported the recommendation to reduce the population objective from 20,000 mule deer to 16,000 mule deer (Figure 5).

Figure 5. Platte Valley herd unit public objective recommendation meeting attendee survey responses to the statement, “Propose to decrease the population objective from 20,000 to 16,000 mule deer for the next 5-years.”

14 March 2014

Dear Landowner,

The Wyoming Game and Fish Department (WGFD) is seeking your assistance in the future management of big game wildlife in your area. During the spring of 2014, WGFD will review the herd unit management objectives for several big game herd units such as Platte Valley mule deer, Elk Mountain pronghorn, and Big Creek pronghorn. Enclosed in this letter you will find a short survey for each herd unit your property is located in, and postage-paid return envelope. Please complete the survey questions, provide additional comments if you desire, and mail the survey in the return envelope.

The herd unit management objective is the “benchmark” which WGFD manages big game wildlife towards. For most big game herd units in Wyoming, WGFD manages big game wildlife towards a numeric management objective, usually identified as a specific postseason population estimate.

Many of Wyoming’s big game wildlife rely on habitat located on private lands. Therefore, landowner opinions on herd unit management objectives are important to WGFD. The comments we receive from your completed surveys will be used in part to formulate WGFD recommendations for the future herd unit management objectives. Changes in the herd unit management objective could result in increasing harvest opportunities to decrease big game numbers, or conversely, changes could result in reducing harvest opportunities in order to increase big game numbers.

We also would like to invite you to one of the upcoming public meetings to discuss herd unit management objectives. Locations and dates are listed below:

- Saratoga Town Hall, March 26, 7:30 p.m.
- Laramie Fire Hall #3, March 27, 7:30 p.m.

Thank you for taking the time to share your thoughts and opinions with us. We hope to see you at one of the upcoming meetings. If you have any questions please contact Will Schultz at 307-326-3020. We look forward to receiving your survey and working with you on the future management of Wyoming’s Wildlife.

Sincerely,

Will Schultz
Saratoga Wildlife Biologist
WS/ws

Platte Valley Mule Deer Herd Unit

Deer Hunt Areas: 78, 79, 80, 81, 83, & 161
Management Objective: 20,000 mule deer
2013 Postseason Population Estimate: 8,800 mule deer
Last Management Objective Review: 1987

1. Please circle the hunt area where the majority of your property is located (see map on back):

Hunt Area 78 79 80 81 83 161

2. How satisfied are you with the current number of mule deer wintering in the Platte Valley herd unit (current estimate is 8,800 mule deer):

☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied

3. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.

☐ There are too many mule deer in the herd unit
☐ There are too few mule deer in the herd unit
☐ Other _____

4. Do you think the herd unit management objective of 20,000 mule deer is:

☐ Too high
☐ Too low
☐ About right

5. Would you support combining Hunt Area 80 and Hunt Area 83 into one hunt area for future hunting seasons?

☐ Yes
☐ No
☐ I am neither for or against

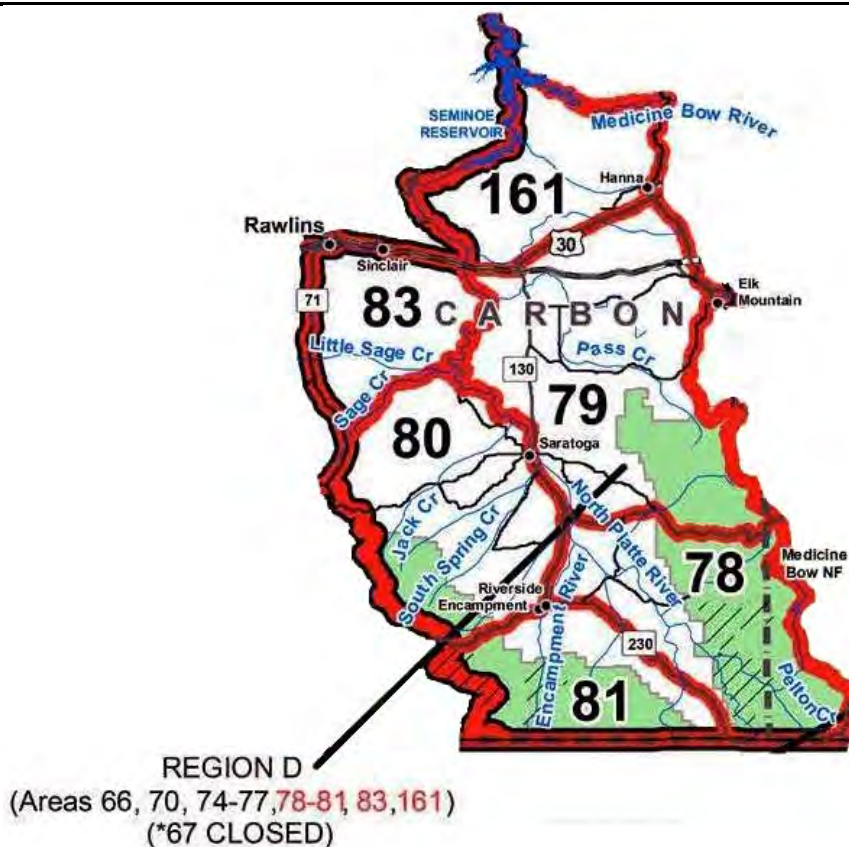

6. Would you support dividing Hunt Area 161 along the Big Ditch? This would result in the southern portion of Hunt Area 161 being combined into Hunt Area 79 and the northern portion of Hunt Area 161 being combined into Hunt Area 70, for future hunting seasons.

☐ Yes
☐ No
☐ I am neither for or against

SURVEY IS CONTINUED ON BACK

7. If you have additional comments, please share them in the space below:

If, in the future, you would like to be contacted through email please provide your name and email address below.

THANK YOU for your participation!

Please circle the hunt area where the majority of your property is located

How satisfied are you with the current number of mule deer wintering in the Platte Valley herd unit

Very Satisfied	5	15%
Somewhat Satisfied	9	26%
Somewhat Dissatisfied	10	29%
Very Dissatisfied	10	29%

3. If you answered somewhat dissatisfied or very dissatisfied, please indicate why

There are too many mule deer in the herd unit	1	5%
There are too few mule deer in the herd unit	20	91%
Other	1	5%

Do you think the herd unit management objective of 20,000 mule deer is

Too high	3	9%
Too low	4	13%
About right	25	78%

Would you support combining Hunt Area 80 and Hunt Area 83 into one hunt area for future hunting seasons

Yes	3	9%
No	6	17%
I am neither for or against	26	74%

Would you support dividing Hunt Area 161 along the Big Ditch? This would result in the southern portion of Hunt Area 161 being combined into Hunt Area 79 and the northern portion of Hunt Area 161 being combined into Hunt Area 70, for future hunting seasons.

Yes	2	6%
No	5	14%
I am neither for or against	28	80%

Comments

We trust your judgement on this! **I hope the G&F continues to search for the reasons for the deer population decline.** **In reference to question 5 & 6: Why? For what reason?: And why was the last management objective review done in 1987?!?! Why are you always 5-10 years behind in your management goals! This may be the reason why WY G&F needs to be more pro-active on their management and in a more timely fashion. By the time G&F reacts it is usually too late. Poor game management!** **Probably better to keep 79 separate.** **As an out of state property owner (the property was a family homestead) Conservation of water is my primary concern. Thank you. -Shirlee Bumpass

I believe at the present time you(G&F) are trying to improve these herd numbers & quality, Keep up the good work! **Like to see the white tail different than mule deer so numbers are not completely destroyed.** **Will: We had quite a few nice bucks in the yard in November. Not any where near the numbers during the winter that we had 10 years ago. We do not see as many but we will have 6-8 pairs during the summer. -Dick Gray PS-Back in May** **Too many hunter's and Mountain Lions.** **I think the G&F does a good job managing all our wildlife.** **I think hunting pressure is too high quota system would provide a better hunting experience and allow for more trophy animals. The lower county north of Sage Creek is better winter habitat and should not be managed the same as higher elevation areas. Good Luck** **How do wintering numbers of mule deer in Platte Valley translate to summer numbers in the higher elevations of hunt areas 80 & 81? (The summer numbers on our property seem very low)** **Don't understand your antelope policy. Have resident herd of 75+or- at all times and I have no say in who I can allow in to hunt them. -DHanson PO Box 388 Saratoga** **The mule deer are being out-competed by the elk. Reduce the elk population & the mule deer population will increase.**

WGFD Public Meeting

Wyoming Game and Fish Department wants to invite you to attend one of the upcoming meetings to discuss herd unit management objective proposals. Earlier this year, we held meetings in these communities asking for your input. Now, we would like to present to you the proposals we developed with the help of your earlier input:

- Recommend increasing the management objective to 800 pronghorn from 600 pronghorn for the Big Creek Pronghorn Herd Unit.
- Recommend maintaining the current management objective of 5,000 pronghorn for the Elk Mountain Pronghorn Herd Unit.
- Recommend decreasing the management objective to 16,000 mule deer from 20,000 mule deer for the Plate Valley Mule Deer Herd Unit.

Your input at these upcoming meetings is important to us! Recommendations, and your input from these meetings, will be presented to the Wyoming Game and Fish Commission in July

For more information please contact:

Carbon County Predator Management District

814 Illinois Street

Rawlins, WY 82301

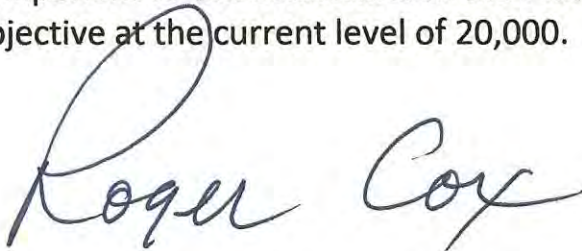

Wyoming Game and Fish Department

Laramie Regional Office

528 S. Adams

Laramie, WY 82070

Today at our regular board meeting we discussed the proposal to decrease the Platte Valley Mule Deer objective from 20,000 to 16,000. In light of the predator control work we have done on the Big Creek antelope project, and the ongoing Platte Valley mule deer fawning area project we are not in favor of the reduction. The Big Creek project has had very favorable results (in fact allowing for a proposed increase of the area 51 antelope objective) and we are hoping that the mule deer project will also be successful enough that it can be expanded. We feel that it is pre-mature to reduce the objective on mule deer at this time. There has been a huge effort to increase this population and a decrease in the objective does not send the proper message. The mule deer is a very important component to the economics of the Platte Valley and we would like to keep the objective at the current level of 20,000.

Herd Unit Management Objective Proposal Meeting
Saratoga Town Hall – 6:00 PM, 22 May 2014

Platte Valley Mule Deer

Current population estimate = 8,800 mule deer

Propose to decrease the management objective from 20,000 to 16,000 mule deer for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Elk Mountain Pronghorn

Current population estimate = 3,800 pronghorn

Propose to maintain the management objective of 5,000 pronghorn for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Big Creek Pronghorn

Current population estimate = 800 pronghorn

Propose to increase the management objective from 600 to 800 pronghorn for the next 5-years.

_____ **I support this proposal**

_____ **I do not support this proposal**

Comments:

The TSJ,CA model was selected to produce the 2014 postseason population estimate. TSJ,SC model aligns very well with the abundance estimates for this herd unit and provides for an excellent "anchor" for future model development.

Management Evaluation

Current Management Objective: 4,000

2014 Post-season Population Estimate: NA

2015 Post-season Population Estimate: NA

Management Strategy: Recreational

Hunter Satisfaction Survey: 60% Satisfied, 19% Neutral, 21% Dissatisfied

The management objective for the Southeast Wyoming Herd Unit is a post-season population objective of 4,000 white-tailed deer. The management strategy is recreational management. The objective and management strategy were last revisited in 1999 and was reviewed in 2015.

Current recommendations are to remove the numeric objective and replace it with hunter/landowner satisfaction survey (Appendix A). This herd objective will be presented to the Game and Fish Commission in July 2015.

Currently there is not a reliable post-season population estimate. This is an open herd with Colorado and Nebraska so trying to model this herd would violate the assumption that it is closed. Seasons are designed to provide opportunity during the mating period when male deer are more vulnerable to harvest. Management is driven primarily by local Department personnel's perception of population trend and landowner tolerance for this species.

Weather

Weather in this herd unit was relatively normal during the past bio-year. Precipitation amounts were average, to slightly above average at all elevations throughout the herd unit for white-tailed deer. No significant prolonged periods of extreme heat or cold temperatures were observed, or extreme snow loading in lower elevation winter ranges. Timing of precipitation and amounts received during key growth periods for cool season grasses and preferred transitional range and winter range shrub species was excellent. Weather patterns most likely had a positive influence on white-tailed deer. Mild fall temperatures and lack of persistent snows allowed for white-tailed deer to spend greater amounts of time on summer and fall transition ranges providing additional relief for winter ranges that have historically been overutilized. For specific meteorological information for the Southeast Wyoming White-tailed Deer Herd Unit the reviewer is referred to the following link: <http://www.ncdc.noaa.gov/cag/>

Habitat

There are no established habitat transects developed for this herd since their main source of diet comes from native rangelands that have been converted to croplands.

Field/Harvest Data

This herd will grow rapidly until densities become too high, then seasons are adjusted to try and decrease the population, or an EHD outbreak occurs that reduces densities. Hunter success is typically around 35% with hunter effort running about 11 days per harvest. Hunting opportunity is limited to private land. Low success and high effort rates are attributed to hunters trying to find a white-tailed deer on public land or trying to harvest a deer during the general season when they are less vulnerable to harvest. Chronic wasting disease is found throughout the herd unit, but to what extent it has on this herd unit is unknown. The long-term prevalence rate average is around 20%, but with a small sample size. There are a limited number of tooth samples so a reliable inference into population performance is not available.

The hunter satisfaction survey showed that 60% of the hunters were either satisfied or very satisfied, which is plausible given the late season opportunity for male deer.

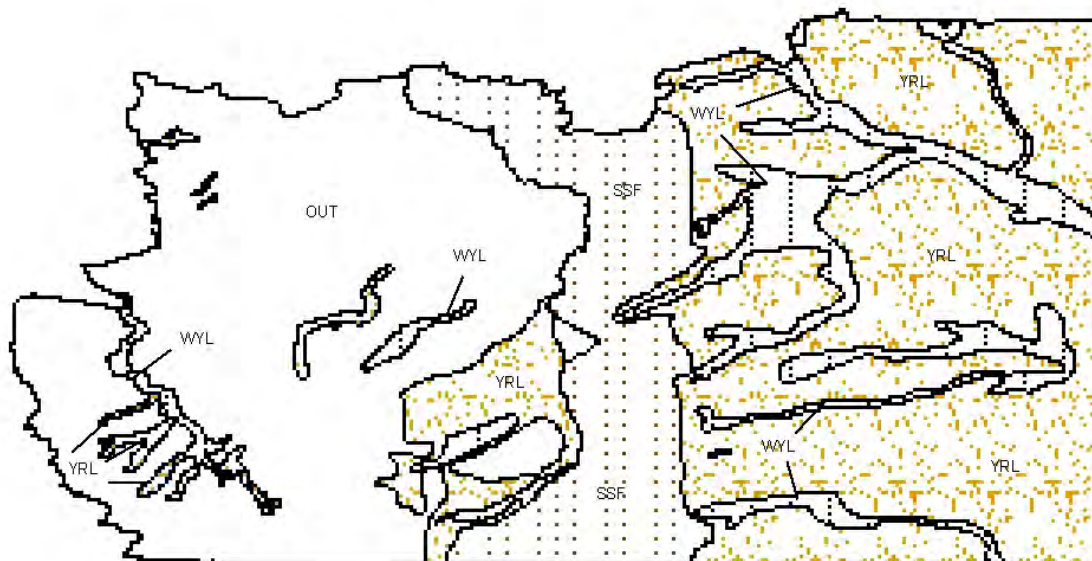

Population

There is not a reliable post-season population estimate. This is an open herd with Colorado and Nebraska so trying to model this herd would violate the assumption that it is closed. Seasons are designed to provide opportunity during the mating period when male deer are more vulnerable to harvest. Management is driven primarily by local Department personnel's perception of population trend and landowner tolerance for this species. There is not enough tooth samples collected in the field to infer any population dynamics.

Management Summary

Population trend varies on weather conditions and disease outbreaks. As densities become too high, the population will typically crash from an EHD outbreak. Severe winter conditions will reduce white-tailed deer numbers if they go into the winter in poor condition. There have been no reports of winter mortalities. There was an EHD outbreak in 2012 that prompted a decrease in Type 8 licenses. However, given the nature of white-tailed deer to rebound quickly from an EHD outbreak, the number of Type 8 licenses in Hunt Area 15 will increase by 50. Based on the Laramie Mountains Herd Unit objective review, Hunt Areas 59,62,63 were combined into Hunt Area 59, and Hunt Areas 64,73 were combined into Hunt Area 64.

For the 2015 season we will try to attain a harvest of around 750 white-tailed deer. Our objective is to provide opportunity and minimize damage.

Herd

Objective

Review

SOUTHEAST WYOMING WHITE-TAILED DEER HERD UNIT AND POPULATION OBJECTIVE REVIEW

Prepared by: Martin Hicks, Wheatland Wildlife Biologist

Current Herd Objective: Post Season Population 4,000 \pm 20% (3,200 – 4,800)

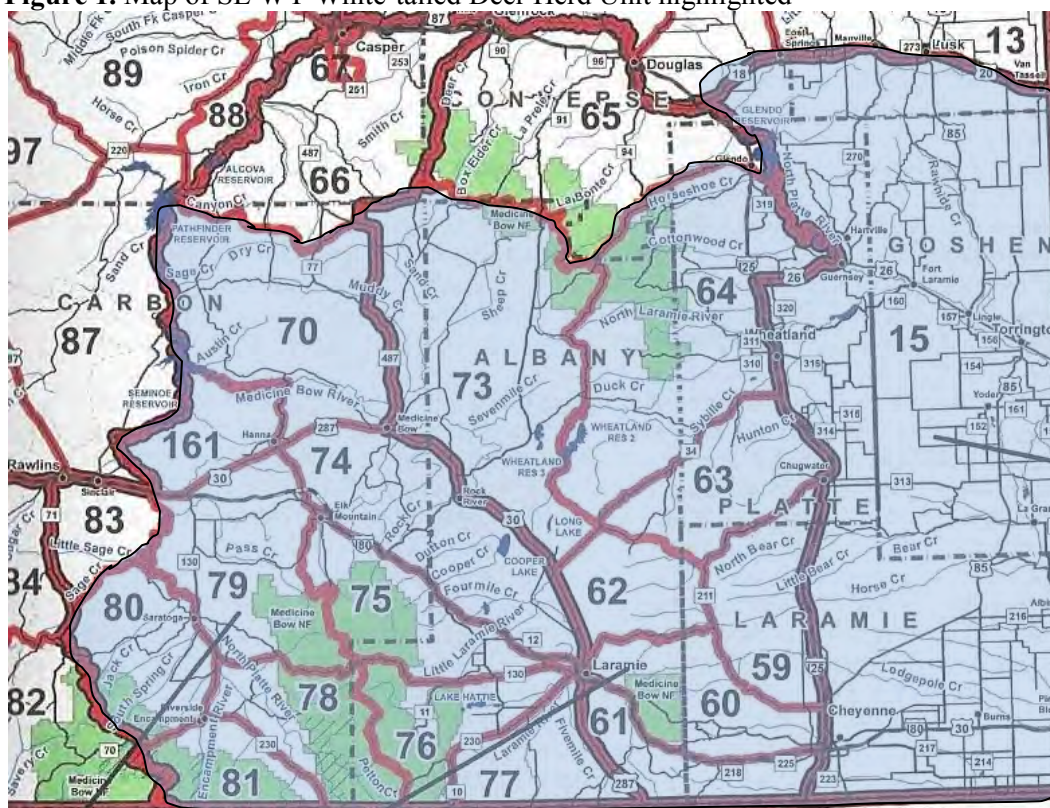

Current Herd Management Strategy: Recreational Management (buck ratio 20-29)

Proposed Herd Objective: Satisfaction Based objective \geq 60% landowner/sportsmen satisfaction

Proposed Herd Management Strategy: Recreational Management (buck ratio 20-29)

The Southeast Wyoming White-Tailed Deer Herd Unit contains Hunt Areas 15, 59, 60, 64, 70, 73-81, 161 is located in southeastern Wyoming (Figure 1.). The management objective for the Southeast Wyoming Herd Unit is a post-season population objective of 4,000 white-tailed deer. The management strategy is recreational management with a post-season male: female range of 20-29 bucks: 100 does. The objective and management strategy were last revisited in 1998.

Figure 1. Map of SE WY White-tailed Deer Herd Unit highlighted

Population Objective Review:

The postseason population objective is developed based upon both biological and social factors, including, but not limited to: winter range carrying capacity, hunter desires, landowner desires and tolerance, land status, and competition with other wild and domestic animals. From 1976-1996 this herd unit was labeled the Laramie River White-tailed Deer Herd Unit, comprised of Hunt Areas 70-81, 83, 161 with a initial objective of 200, then increased to 1,000 in 1986. In 1998 Hunt Areas 15, 16, 55, 57 (combined into Hunt Area 15 in 2014) 59-64 (Hunt Areas 59, 62, 63 will be combined into Hunt Area 59 and Hunt Areas 64 and 73 will be combined into Hunt Area 64 for the 2015 season) were added to create the SE WY WTD Herd Unit with a new objective of 4,000.

Current Management Strategy:

There is not a reliable post-season population estimate. This is an open herd with Colorado and Nebraska, so trying to model this herd would violate the assumption that the population is closed. Seasons are designed to provide opportunity during the mating period when male deer are more vulnerable to harvest. Management is driven primarily by local Department personnel perception of population trend and landowner tolerance for this species.

Recommended Hunt Unit Objective and Management Strategies by Herd Unit:

Due to our inability to manage this herd unit and lack of adequate population data to derive a post-season population objective we recommend changing the post season population objective of 4,000 white-tailed deer to a satisfaction based objective. This objective uses a sportsmen/landowner surveys to determine levels of satisfaction and has a target goal of 60% or greater satisfaction level. Satisfaction surveys have been conducted for the past 4 years for big game herd units (Figure 2). The four-year average for sportsmen satisfaction is 62%. Key landowners that provide habitat for the majority of white-tailed deer will be mailed a satisfaction survey to gauge their level of satisfaction with white-tailed deer herds that occupy their property.

Figure 2. Sportsmen Satisfaction Survey with a target goal of 60% satisfied (2011-2014).

Landowner, Agency, and Public Involvement:

A power point presentation was prepared on the background of the Southeast Wyoming White-tailed Deer Herd Unit and presented at the following public meetings: Wheatland, Torrington, Laramie and Cheyenne in January 2015. In addition a survey requesting input on the future management of this herd was handed out to the attendees. There were a total of 17 people in attendance at the four public meetings. There was very little interest or concern in the future management of the SE WY WTD Herd Unit gathered from the public at the meetings and no surveys were returned. At these meetings the public was informed about herd objectives and the alternative and secondary objectives available as provided by Wildlife Administration. Department personnel preferred to abandon the current objective of 4,000 white-tailed deer and adopt an alternative objective of sportsmen/landowner satisfaction survey. No federal or state agencies were involved because the majority of occupied habitat is on private land. A copy of comments, public meeting attendants and the survey can be found in Appendix A.

An additional four public meetings were held the week of March 23, 2015 during the Public Information Gathering Meeting process for the 2015 hunting season proposal. Meetings were held in Wheatland, Torrington, Cheyenne and Laramie. In total there were 67 people in attendance (Appendix B), again there was little concern or comments regarding the future management of the Southeast Wyoming White-tailed Deer Herd Unit. Three surveys were returned (Appendix B), two were in support of the proposed objective and one was neutral.

Landowner/Sportsmen Survey:

Notification was sent to all local newspapers along with posters distributed throughout the different communities inviting the public to attend one of four public meetings that were held in January and March. No surveys were returned from the January meetings and three were returned from the March meetings.

Recommendation:

In summary we propose to eliminate the numeric objective of 4,000 white-tailed deer and go with an alternative objective of a landowner/sportsmen survey. Surveys will be mailed to landowners that have larger acres (>160 acres) of contiguous white-tailed deer habitat in Platte, Goshen, Laramie, Albany and Carbon counties. The secondary objectives of habitat indices, male “quality” and harvest statistics do not appear to be a reliable indicator of population performance for the following reasons. There are currently or planned habitat transect associated with white-tailed deer forage needs. The sample size of buck “quality” is well below an adequate sample size to derive any inferences to population performance. A target for harvest success would be difficult to gauge or determine given success typically runs around 30%. What a realistic goal should be would be a guess and not have any relevance on how this herd would be managed. Trends in success and effort would still be a tool to assist in determining license numbers and season length.

This recommendation is based upon a lack of adequate population data to derive reliable population estimate. Based on the outreach effort and past comments from landowners and sportsmen there is less emphasis of concern placed on white-tailed deer compared to other big game species in southeast Wyoming.

February 25, 2015

The following comments were gathered from 4 PIGMs held throughout January 2015 regarding management of the Southeast Wyoming White-tailed Deer Herd Unit

Torrington, January 14, 2015

Comments:

- 1) Have you had any trouble with Chronic wasting disease? We don't test as many white-tails. But they seem to replace themselves easily. Blue tongue is the thing that seems to kill white-tails.
- 2) Does blue tongue kill both mule deer and white-tail?
- 3) One guy has 160 acres and cannot get a landowner's permit. The bucks we see look like big jackrabbits. We've been seeing more mule deer because there are fewer white-tails.
- 4) How is the antler point restriction coming along near Miracle Mile? Corey said there are not a lot of immediate or great results from the point restrictions.
- 5) How many people applied for the 500 Type 3 licenses? Martin said these are very popular licenses and they all go in the draw. I don't have any white-tail left on my land because they cut down all the Russian olive trees. Can landowners get a preference license? You would have to get a general license.
- 6) You don't know if you have 4,000 deer? There is not a lot of money to monitor white-tailed deer. They reproduce easier than mule deer. They are not as sensitive to environment changes like mule deer are.
- 7) How many licenses will be available for 2015? We will have a meeting in March to determine the upcoming season structures.

Cheyenne, January 15, 2015

Comment:

- 1) I keep hearing there are so many white-tailed deer (near Casper Mountain) but I have only seen a few in the past four years. Where are they? Torrington and Lusk is white-tailed habitat.

Laramie, January 16, 2015

- 1) Area 79, the population is going down. You rarely see any deer anymore. The lion and bear populations are also hurting these deer.

Wheatland, January 17, 2015

Comment:

- 1) We had one white-tailed deer hunter this year because we didn't have any deer. The coyotes are unreal in Cottonwood area. I saw 3 coyotes take a 10-point buck. We are going to back off on white-tails the way it is looking.

Southeastern WY white-tailed deer Herd Unit Objective Review

1. How satisfied are you with the current SE WY White-tailed deer population:

☐ Very Satisfied ☐ Somewhat Satisfied ☐ Somewhat Dissatisfied ☐ Very Dissatisfied

2. If you answered somewhat dissatisfied or very dissatisfied, please indicate why.

☐ There are too many animals in the population

☐ There are too few animals in the population

☐ Other _____

3. What do you think about the current post-season population objective of 4,000 (3,200-4,800) white-tailed deer?

☐ Current Herd Objective Needs to Increase

☐ Current Herd Objective Needs to Decrease

☐ Current Herd Objective is Acceptable

☐ Current Objective needs to Change to Satisfaction based Objective

4. If you have additional comments, please share them in the space below:

If, in the future, you would like to be contacted through email please provide your email address below. _____

Please Mail To: WGFD, 528 South Adams, Laramie, WY 82070

THANK YOU for your participation!

2015 Herd Unit Management Objective Proposal Sportsmen Survey

Southeast Wyoming White-tailed Deer Herd Unit

Current population estimate = unknown

Management Strategy: Recreational

Propose to change herd objective strategy from a numeric objective of 4,000 WTD to a landowner/sportsmen satisfaction survey (target goal of $\geq 60\%$ satisfied)

☒ I support this proposal

☐ I do not support this proposal

Comments:

Sounds good to me.

Can you get estimates on WTD based on deer harvest surveys in WY? For instance, could you ask on general deer hunting surveys if people harvested a WTD, and if so where (unit/drainage etc) it was harvested? This may not be real accurate but it's a start.

If, in the future, you would like to be contacted through email please provide your email address below.

2015 Herd Unit Management Objective Proposal Sportsmen Survey

Southeast Wyoming White-tailed Deer Herd Unit

Current population estimate = unknown

Management Strategy: Recreational

Propose to change herd objective strategy from a numeric objective of 4,000 WTD to a landowner/sportsmen satisfaction survey (target goal of $\geq 60\%$ satisfied)

☐ I support this proposal

☐ I do not support this proposal) *Neutral on this - see comments*

Comments:

*However they are managed, harvest should be increased on whitetails.
Basically work to lower WTD numbers.*
